

# Production of the Strangest Baryons on the Proton with CLAS12 (PR12-12-008)

Michael Dugger, Arizona State University

Dan Watts, Edinburgh University

John Goetz, University of California at Los Angeles

Lei Guo, Florida International University

Eugene Pasyuk, Jefferson Lab

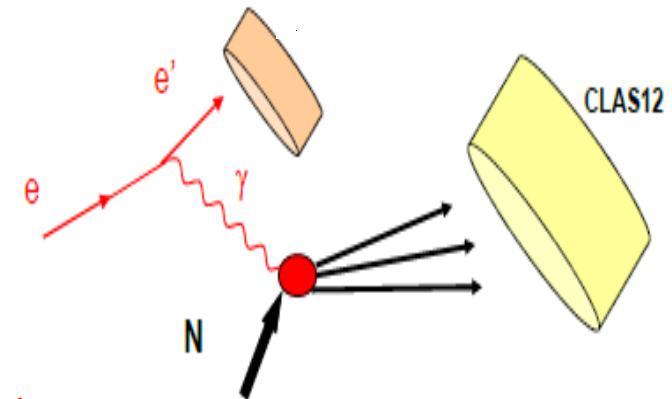

Igor Strakovsky, George Washington University

Veronique Ziegler, Jefferson Lab

On behalf of the Very Strange Collaboration  
and the CLAS Collaboration

# Production of the Strangest Baryons on the Proton with CLAS12

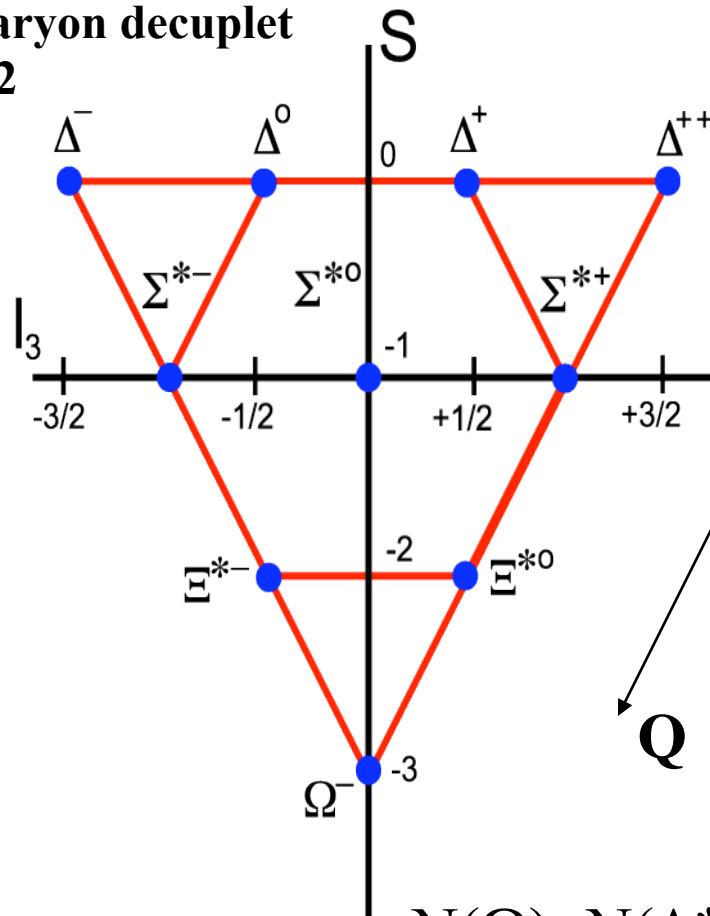

- Motivation
  - $\Omega^-$  cross section measurement of  $\gamma p \rightarrow \Omega^- K^+ K^+ K^0$  and study of production mechanism ( $\Delta S = -3$ )
  - Cascade physics
    - Excited cascade resonances (Spin-parity measurements, searches for missing states)
    - Polarization measurement of  $\Xi^-$
- Existing data (CLAS)
- Simulation
  - Rate and background estimation
- Experimental setup and projected results

# Motivation: The Baryon Ground States in the Quark Model

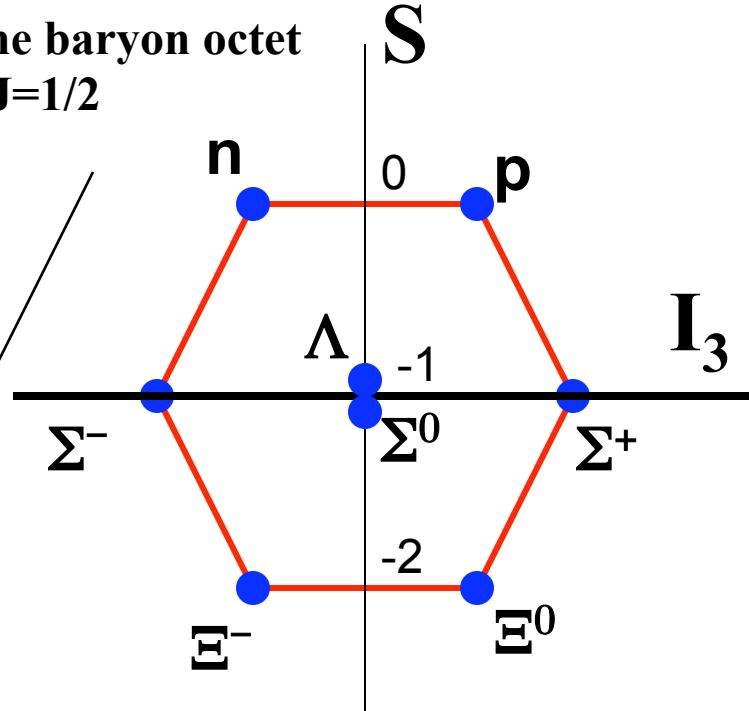

**The baryon decuplet**

$J=3/2$

**The baryon octet**

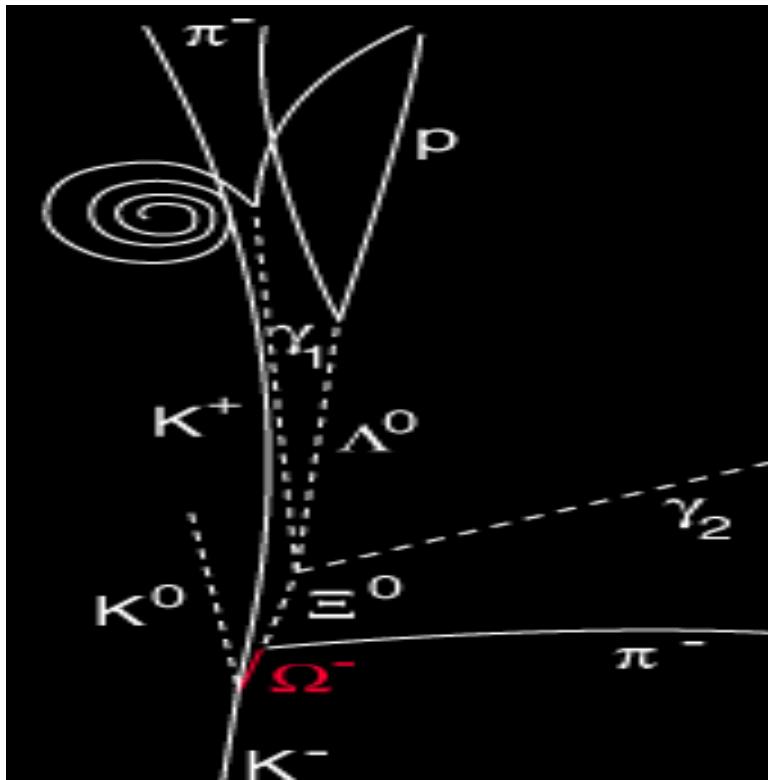

$J=1/2$

$$N(\Omega) = N(\Delta^*)$$

$$N(\Xi) = N(N^*) + N(\Delta^*)$$

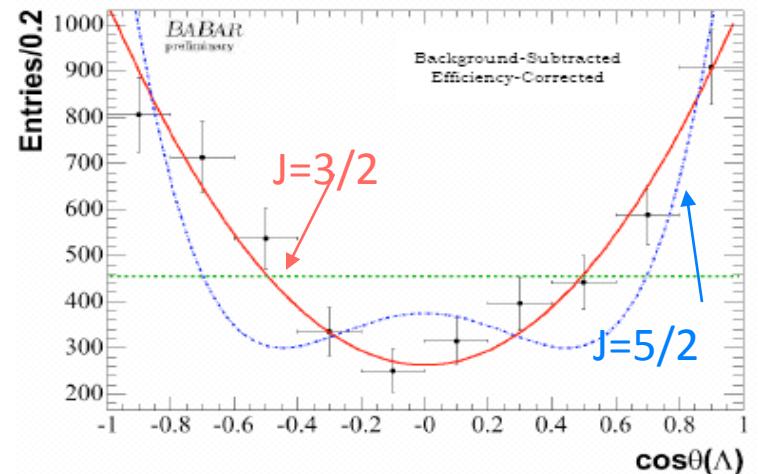

# Motivation: History of $\Omega^-$ (sss) Baryon

Barnes et al, PRL 12:204, 1964,

$$K^- p \rightarrow K^0 K^+ \Omega^-$$

First measurement of  $J(\Omega^-)$   
at SLAC:  $\Xi_c^0 \rightarrow \Omega^- K^+, \Omega^- \rightarrow \Lambda K^-$

$$J(\Omega^-)=3/2, \text{ if } J(\Xi_c^0)=1/2$$

Aubert et al, PRL.97:112001, 2006

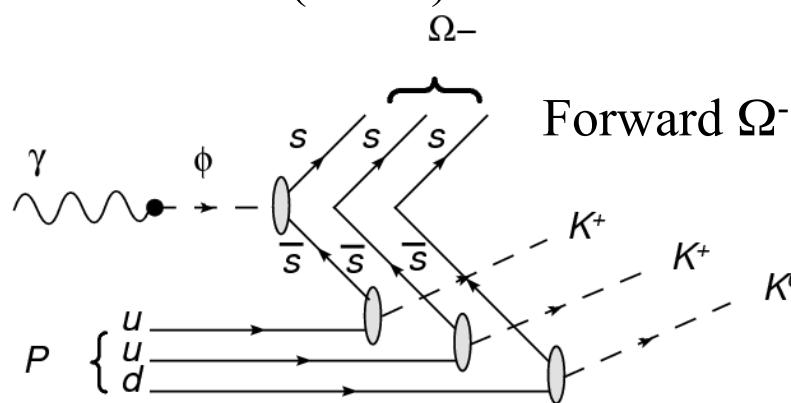

# Motivation: Excited (PDG\*\*\*) $\Omega/\Xi$ Baryons (half a century later)

	$(J)^P$	$M(\text{MeV})$	$\Gamma(\text{MeV})$
$\Omega(2250)$	? ?	2250	
$\Xi(1530)$	$(3/2)^+$	1530	9.1
$\Xi(1690)$	$(1/2?)^?$	1690	<30
$\Xi(1820)$	$(-3/2?)^-$	1823	24
$\Xi(1950)$	(?)?	1950	60
$\Xi(2030)$	$(>=5/2)?$	2025	20

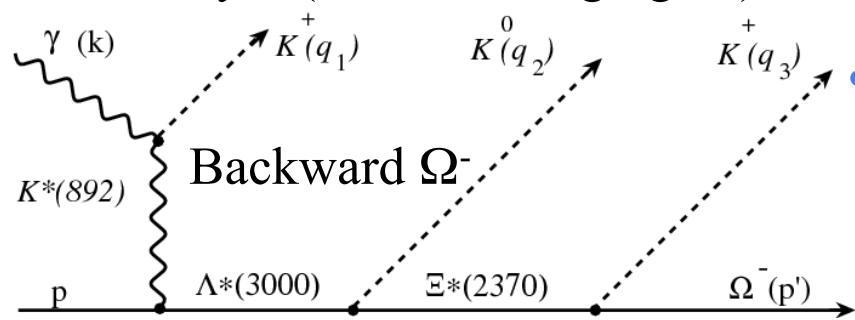

- Very few  $\Omega/\Xi$  baryons have been identified in the last 50 years
- Even fewer have their quantum numbers determined
- Mass splitting measurement for  $\Xi$  needs corroboration
- Kaon beam was the primary source for the discoveries
- Photon beam could be a powerful alternative

# Motivation: $\Omega^-$ (sss) Cross Section and Production Mechanism

A. Afanasev (VMD):

V. Shklyar (Effective Lagrangian)

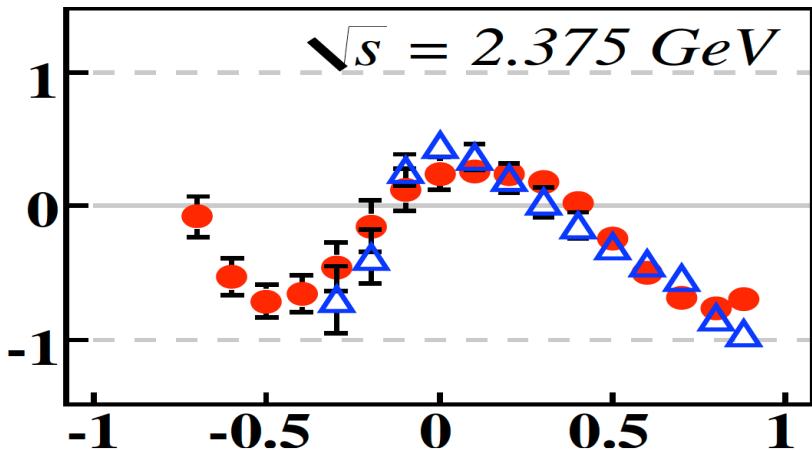

Results from W. Roberts are comparable

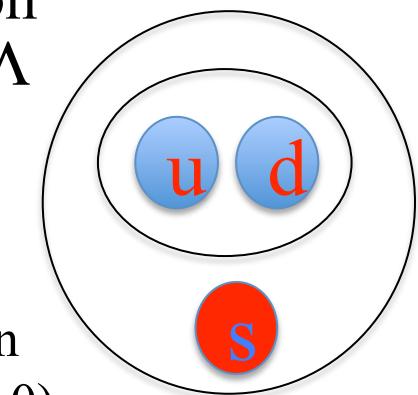

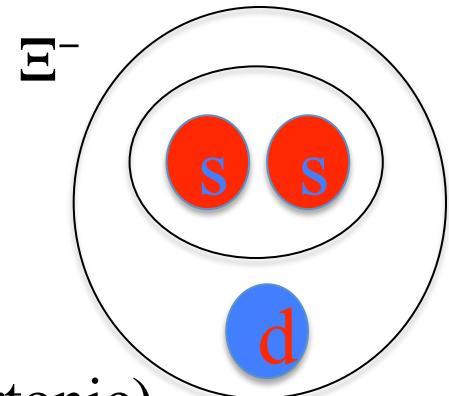

- Production mechanism for  $\Omega^-$  in photoproduction unknown but extremely interesting:  
None of the constituent quark ( $s$ ) is from the target ( $\Delta S = -3$ )
- Models imply different angular distributions
- Various models (by co-authors) predict  $\sigma \sim 0.3\text{-}2\text{nb}$  at  $E\gamma \sim 7\text{GeV}$   
SLAC upper limit: 17nb@20GeV  
Abe et al, PRD32, 2869 (1985)

# Motivation: Hyperon Polarization

- Diquark models:
  - “Good” diquark: isospin 0 and spin 0
  - $\Lambda((ud)s)$  polarization comes from s
  - $\Xi(u/d(ss))$ , polarization comes from u/d?
- Purpose of studying  $\Xi$  polarization
  - Probe production mechanism (hadronic/partonic)
  - Understand the origin of hyperon polarization

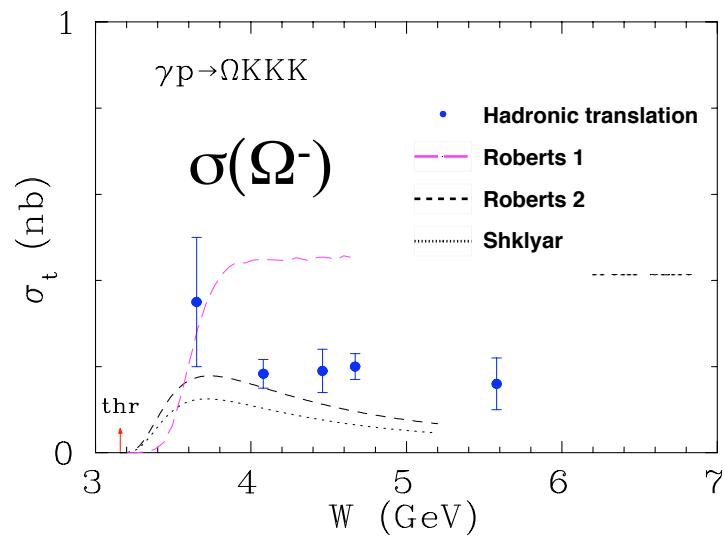

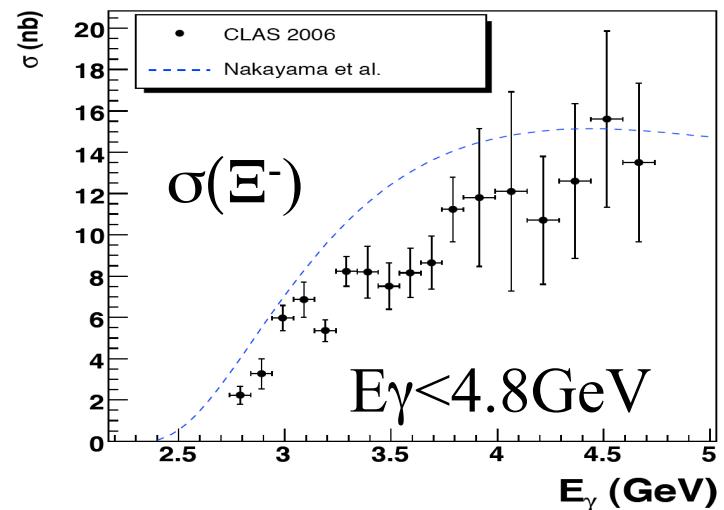

Induced  $\Lambda$  polarization  
(CLAS Collaboration  
PRC81, 025201(2010))

# Cross Sections: Rate Estimation

- Assuming  $\sigma(\Omega^-) \sim 0.3\text{nb}$   
(Afanasev, Roberts, Shklyar)
- $\sigma(\Xi^-) \sim 15\text{nb}$  (Oh, Nakayama, et al.)
  - SLAC inclusive: 117nb@20GeV
- $\sigma(\Xi^-(1820/1690))$ : around 1-5nb  
(Oh et al)
- Luminosity:  $10^{35}\text{cm}^{-2}\text{s}^{-1}$
- FT acceptance:  $2.5\text{--}4.5^\circ (\theta)$   
 $0.5\text{--}5.0\text{GeV} (E_{e'})$
- $\Omega^-$  rate: 90/hr
- $\Xi^-$  rate: 3.6k/hr
- $\Xi^-(1690)/\Xi^-(1820)$ : 0.2-0.9k/hr  
CLAS12 acceptance not yet accounted for

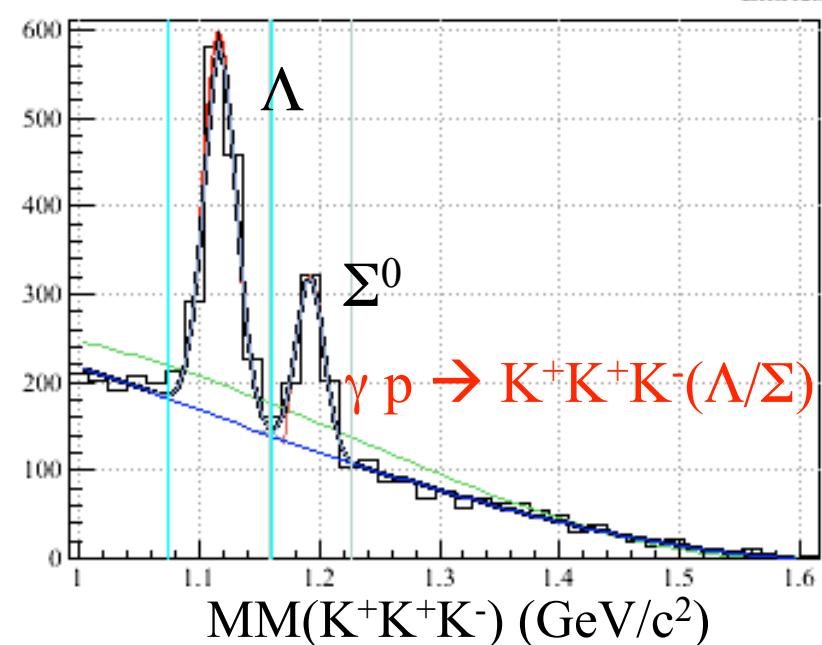

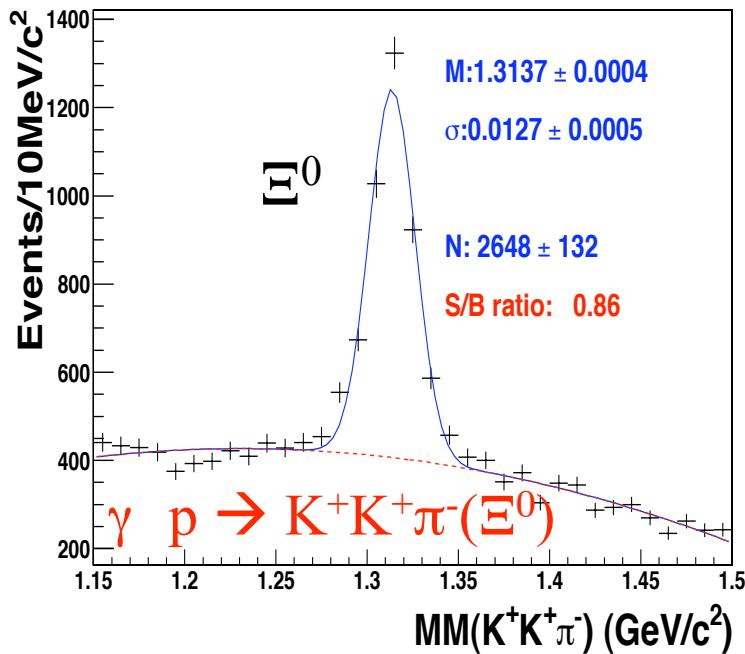

# Existing Data(CLAS)

## Search for Excited Cascade Resonances

$$\Xi^{*-} \rightarrow \pi^- \Xi^0, \Lambda/\Sigma K^-$$

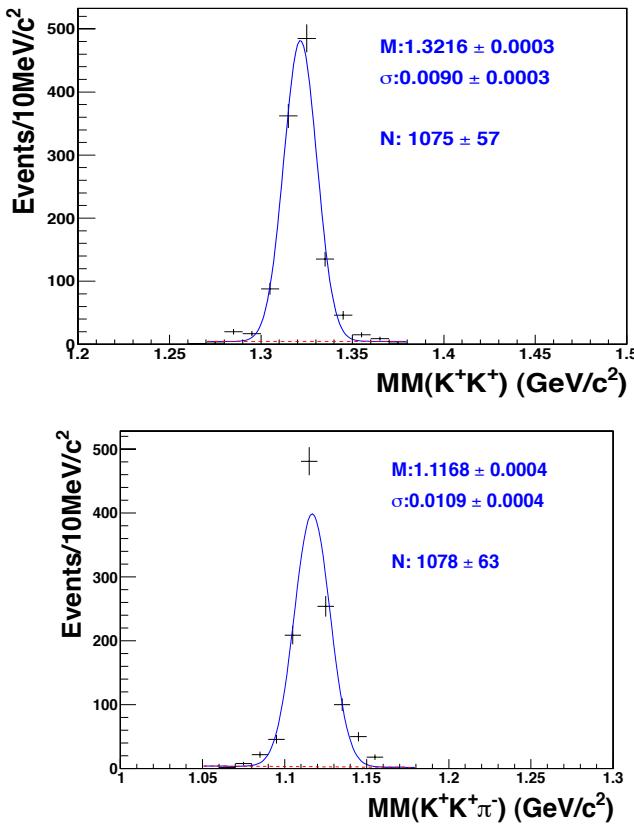

$E_\gamma: 3.6-5.4\text{GeV}$

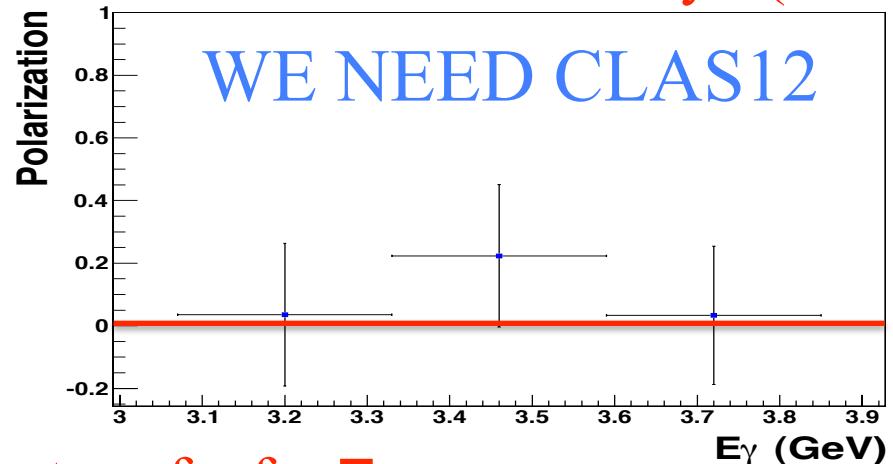

- $\Xi^0/\Lambda/\Sigma$  decay chain not detected (can not determine  $J^P$ )
- Limited by beam energy, excited states unlikely in CLAS
- Expected total number of  $\Omega^-$ : 1 @ CLAS/g12 data

We NEED CLAS12: predicted cross sections at higher  $E_\gamma$ , better acceptance ...!

# Existing Data(CLAS): $\Xi^-$ Induced Polarization in Photoproduction

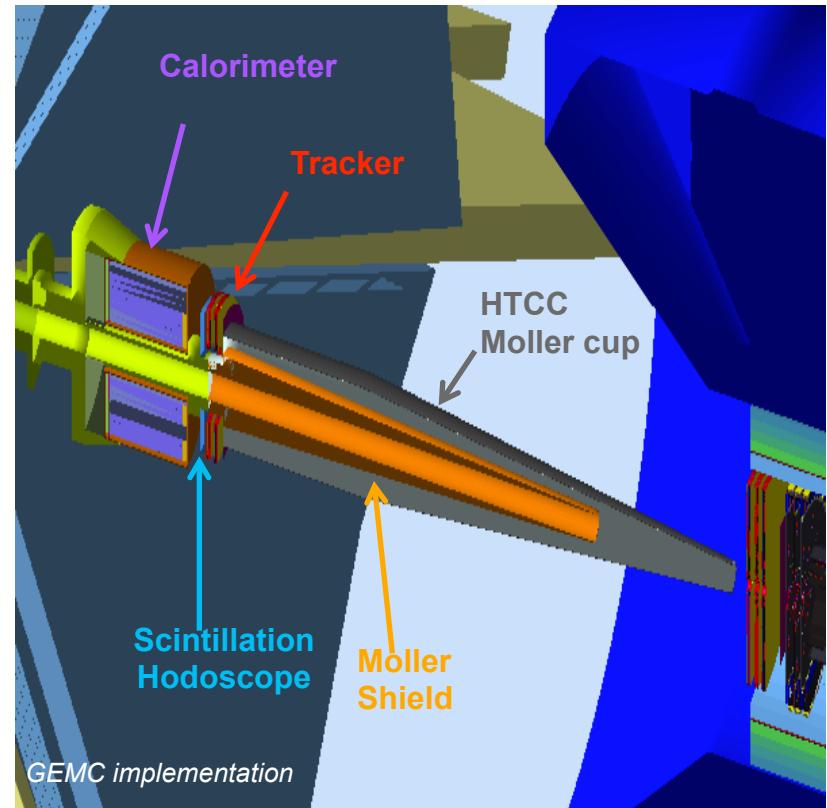

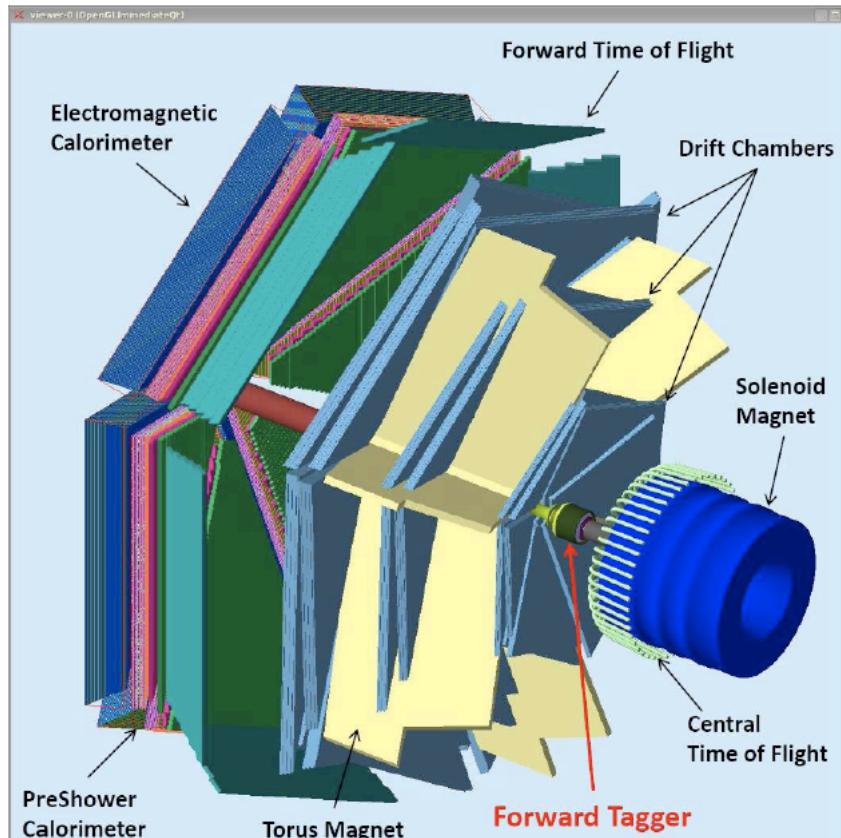

- Data virtually background free (double kinematic constraints)
- Without beam/target polarization,  $\Xi^-$  should not be polarized, if our naïve di-quark picture is correct,
- Statistics limited to study  $P(\cos\theta^*)$

CLAS12 (with FT): polarization transfer for  $\Xi^-$   
 $P_\gamma(10\text{-}85\%)$ , known on a event by event basis

# Experimental Set Up: CLAS12 Forward tagger(FT)

$E_e$ : 0.5-6.0GeV

$\theta_e$ : 2.5°-4.5°

$E_\gamma$ : 5.0-10.5GeV

$P_\gamma$ : 10-85%

$Q^2$ : 0.01-0.3GeV<sup>2</sup>

FT: not CLAS12 baseline equipment.  
under construction

# Benchmark Reactions and Trigger

- $\Omega^-$  measurement

- $\Xi^-$  polarization measurement

- Excited Cascade resonances

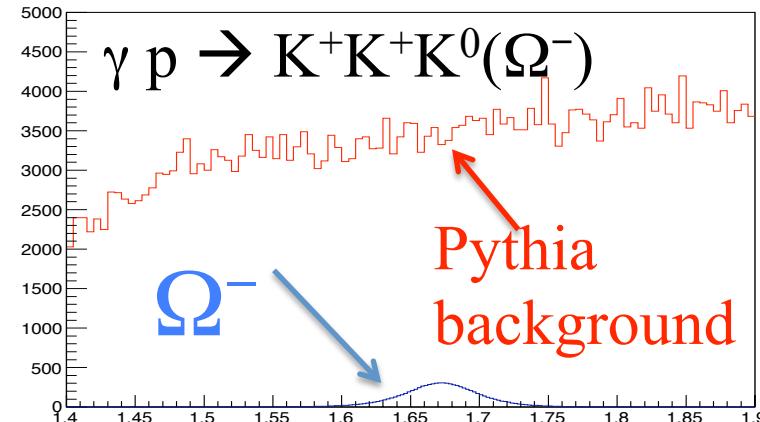

## Trigger setup

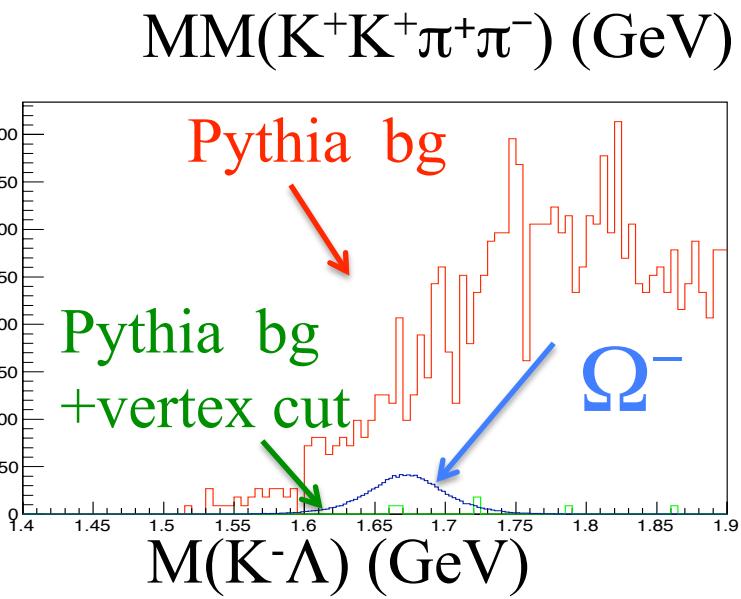

- All reactions of interest need multiple charged hadrons detected
- Minimum requirement:
  - 2-prong+FT
  - Similar to the E12-11-005 (CLAS12 meson spectroscopy) requirement
  - Expected trigger rate <10KHz

# Simulation and Background Estimation ( $\Omega^-$ )

- Main source:  
Hadronic background
  - Pythia Simulation:  
 $\gamma p \rightarrow p + \text{anything}$
  - S/B ratio 1:10
- ↓  
 $\Lambda$  cut and vertex cut

- $\gamma p \rightarrow K^+ K^+ K^0 \bar{K} (\Lambda)$
- Data almost **background free** if vertex cut is included
- Vertex resolution: 1.0mm
- Detached vertex cut: 5mm  
(5-10% loss of data)

# Spin-Parity Determination of $\Xi^*$

- Spin can be measured by angular distributions (PWA)
- Parity measurement challenge: Minami ambiguity

$\Xi^* \rightarrow Y(1/2^+) + M_1(0^-)$ : two solutions  $J^P$

- Double Moment Analysis (DMA)

$Y(1/2^+) \rightarrow B(1/2^+) + M_2(0^-)$

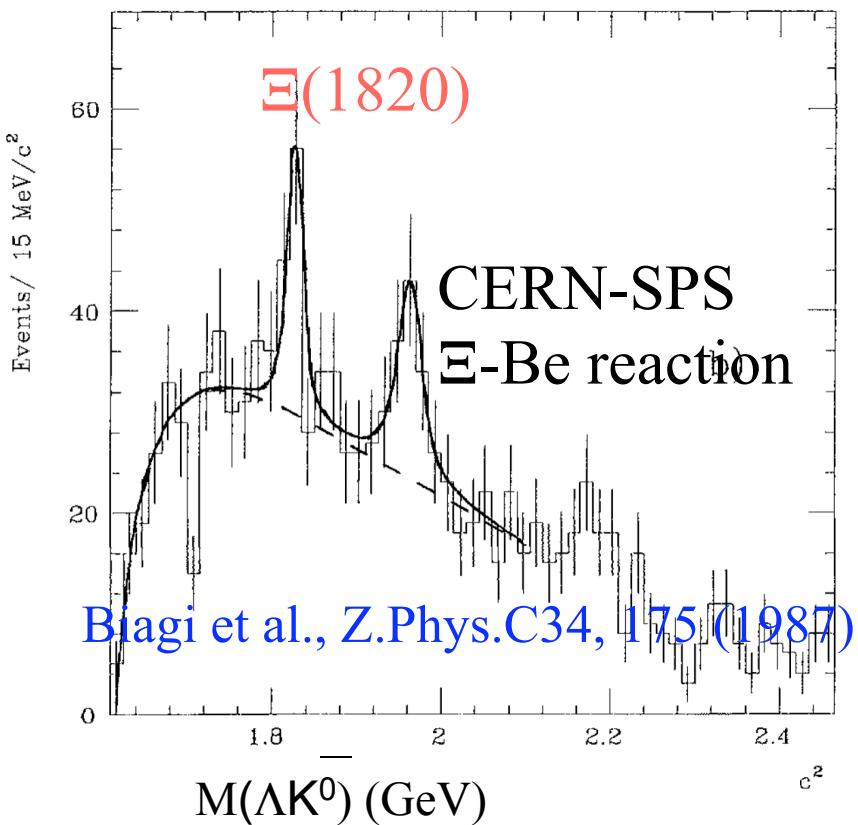

Double moments:  $H(lmLM) = \sum D^L_{Mm}(\theta_1, \phi_1) D^l_{m0}(\theta_2, \phi_2)$

DMA:

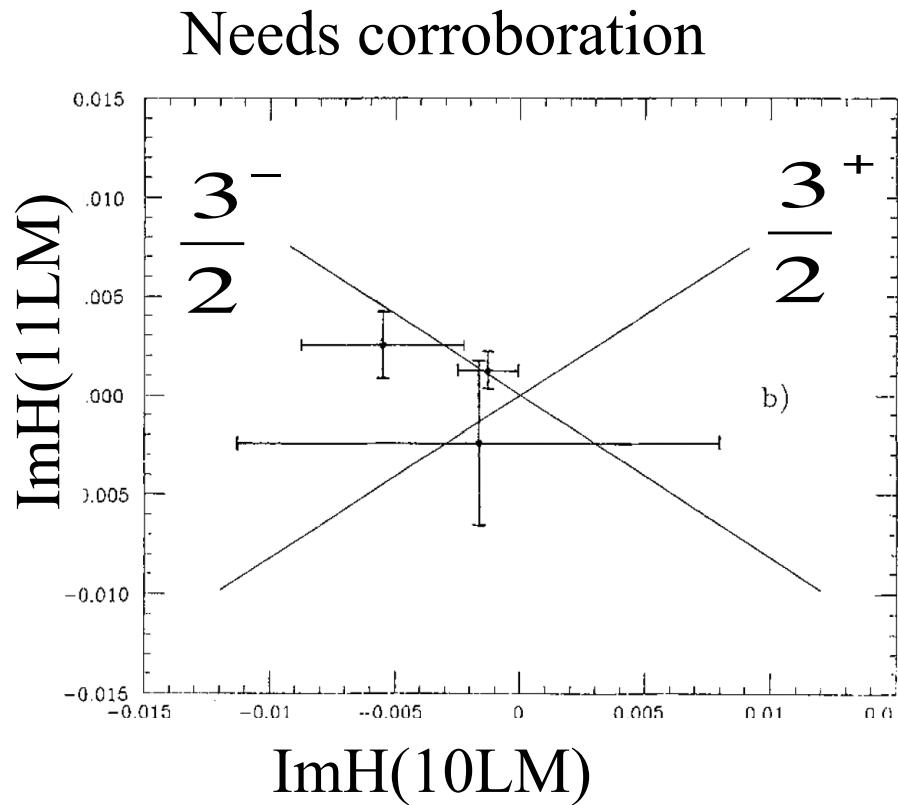

$$H(11LM) = P(-1)^{\frac{J+1}{2}} \frac{2J+1}{\sqrt{2L(L+1)}} H(10LM)$$

- Linear dependence gives simple, multiple tests for  $J, P$  for any odd  $L \leq 2J$  and  $M \leq L$

# Example: Parity Measurement of $\Xi(1820)$

$\Xi(1820) \frac{3}{2}^-$  counts: ~50  
Need to detect whole decay chain

CLAS12 estimate: ~12k  $\Xi(1820)$   
with complete decay chain  
At CLAS12 (80 beam days)

# Beam Time and Expected Particle Rate

	<b>Detected particles</b>	<b>Measured Decays</b>	<b>Overall Efficiency</b>	<b>Rate/hr</b>	<b>Total Detected</b>
$\Omega^-$	$K^+K^+K^0$		$\sim 3.9\%$	$\sim 3.6$	$\sim 7k$
$\Omega^-$	$K^+K^+K^0K^-$	$\Omega^-$	$\sim 0.5\%$	$\sim 0.5$	$\sim 1k$
$\Xi^-$	$K^+K^+\pi^-$	$\Xi^-$	$\sim 9.3\%$	$\sim 440$	$\sim 0.9M$
$\Xi^-(1530)$	$K^+K^+\pi^-$	$\Xi^-(1530)$	$\sim 7.4\%$	$\sim 140$	$\sim 270K$
$\Xi^-(1820)$	$K^+K^+K^-p$	$\Xi^-(1820)\Lambda$	$\sim 0.63\%$	$\sim 6$	$\sim 12K$

- Assuming half field, FastMC used
- Vertex Efficiency/Branching Ratio included
- Approved beam time for E12-11-005 (80days) is sufficient for us to achieve all goals.

# Expected Results: $\Xi^-$ Polarization and $\Xi^-(1820)$ Spin-Parity Measurement

- $\Xi^-$  polarization measurement:  
 (should be  $E_\gamma$  dependent)

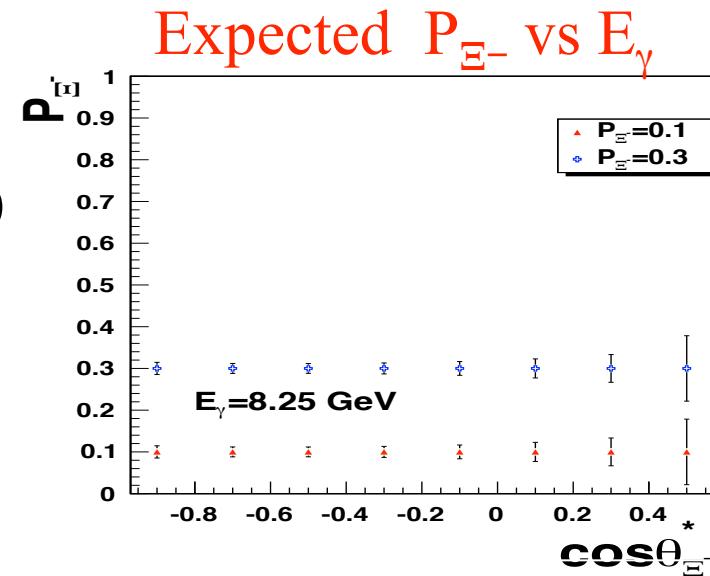

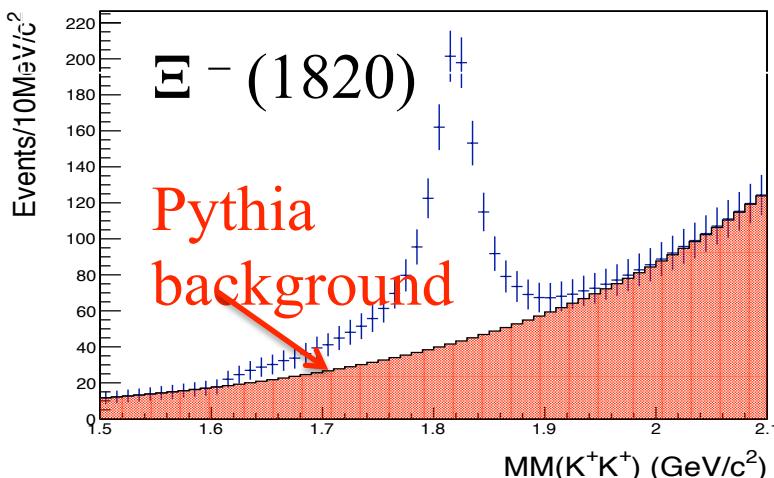

$$\gamma p \rightarrow K^+ K^+ \Xi^- \rightarrow K^+ K^+ \pi^-(\Lambda)$$

- $\Xi^-(1820)$  double moments

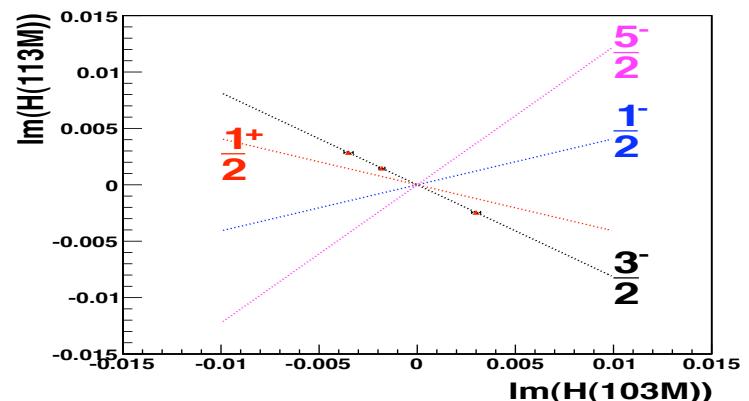

$$\gamma p \rightarrow K^+ K^+ \Xi^-(1820)$$

$$\Xi^-(1820) \rightarrow K^-(\Lambda \rightarrow \pi^- p)$$

## Expected $M(\Lambda K^-)$ spectrum

## Expected double moments ( $L=3$ )

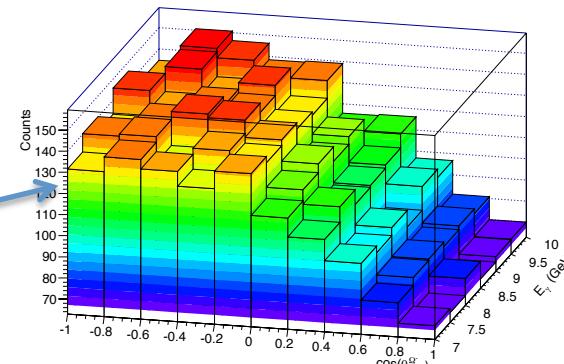

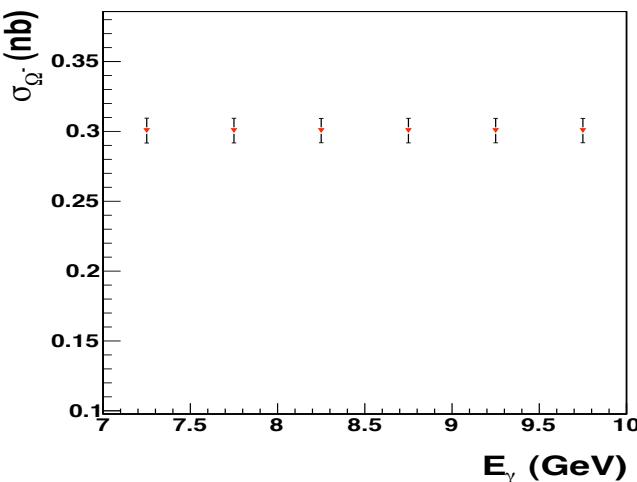

(statistical uncertainty only) 17

# Expected Results: $\Omega^-$ Mass Spectrum and Cross Sections

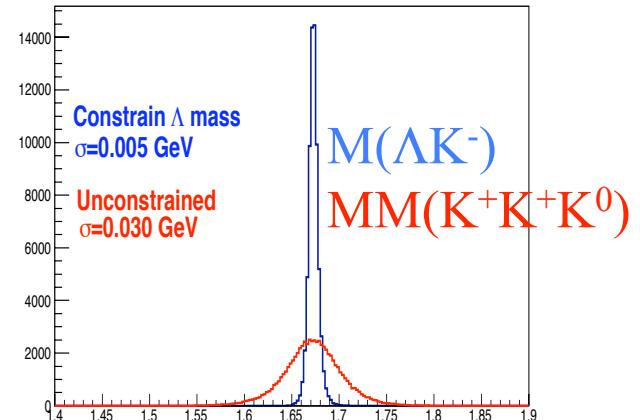

- $\Omega^-$  Measurement:
  - When four kaons detected, spectra is expected to be **background FREE**

Expected Cross section Measurements  
(Assuming no energy or angular dependence)

Detect  $K+K^0 K^- K^+$

- Constraining the  $\Lambda$  mass improves the resolution
- Improvement expected with kinematic fitting

# Expected results: $\Xi$ and $\Xi(1530)$ cross section measurements

- $\Xi^-$  Measurement:

$$\gamma p \rightarrow K^+ K^+ \Xi^- \rightarrow K^+ K^+ \pi^-(\Lambda)$$

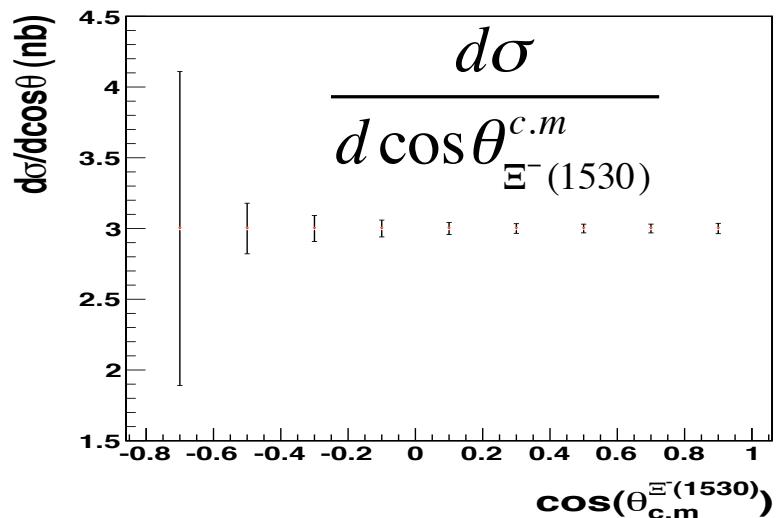

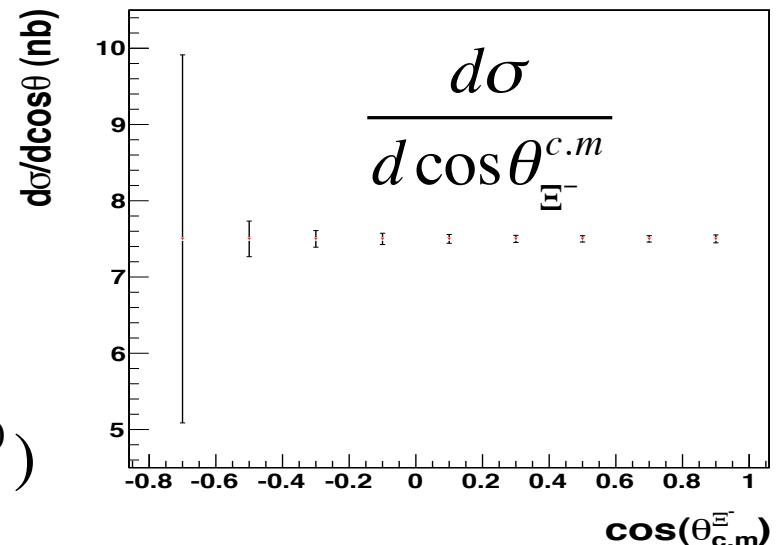

$$\gamma p \rightarrow K^+ K^+(\Xi^-)$$

- $\Xi^-(1530)$  Measurement

$$\gamma p \rightarrow K^+ K^+ \Xi^-(1530) \rightarrow K^+ K^+ \pi^-(\Xi^0)$$

$$\gamma p \rightarrow K^+ K^+(\Xi^-(1530))$$

- Simulation assumed no angular dependence:
  - Measurement in backward angle (CM) should have smaller uncertainty than shown due to larger expected cross section

# Summary

- $\Omega/\Xi$  baryons are underexplored
- CLAS12 is well suited to study  $\Omega/\Xi$  physics using the forward tagger
- $\Omega^-$ : Cross section can be measured (almost background free)  
production mechanism can be investigated
- Excited cascade resonances:  
Spin-Parity can be determined
- $\Xi(1320)$  polarization: insight to the production mechanisms
- Mass splitting for multiple  $\Xi$  doublets can be measured
- Experimental set-up compatible with the meson experiment
- Total request beam time:
  - 80 days in parallel with the approved meson experiment

# Backup Slides

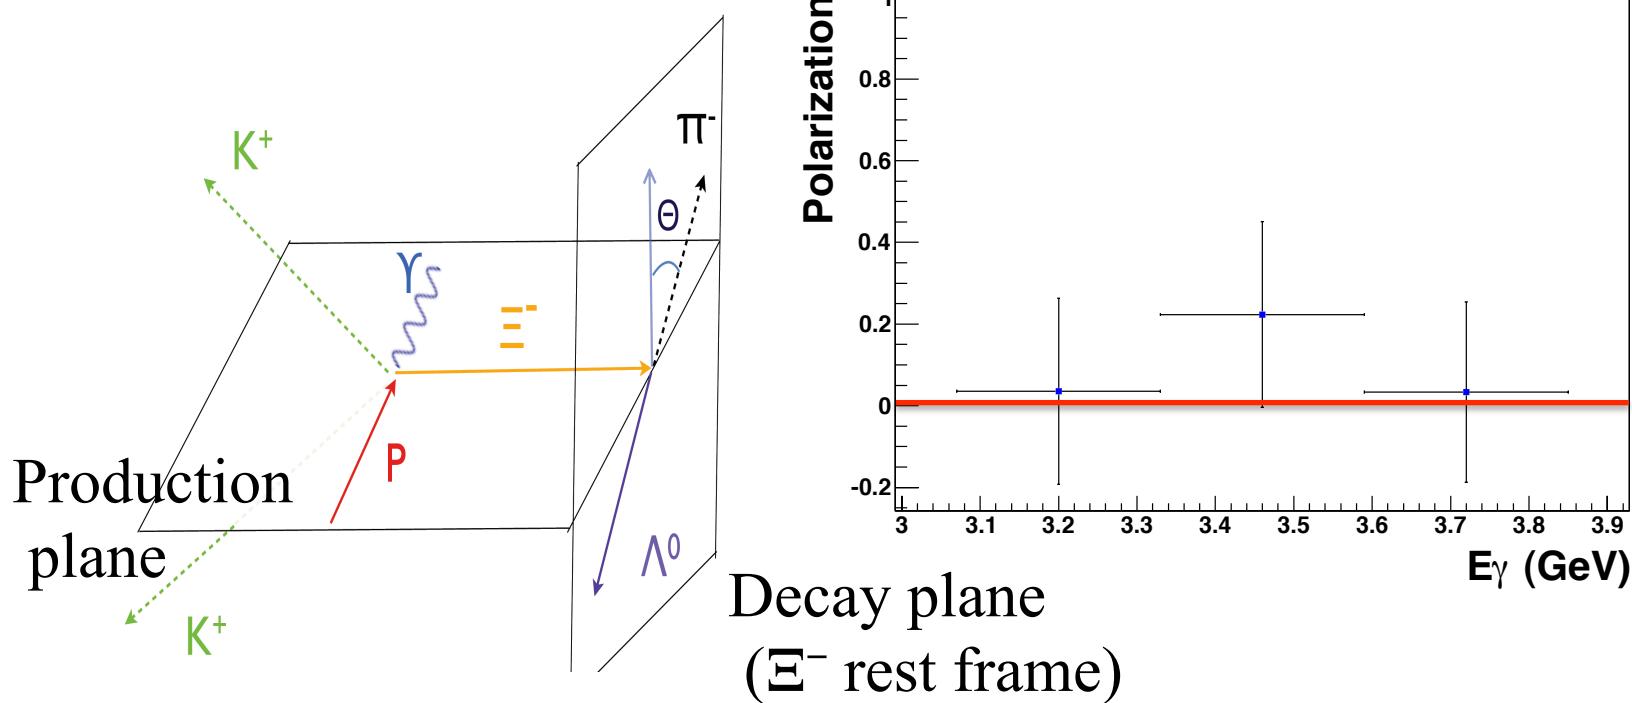

# Motivation: Hyperon Polarization

- Diquark models:
  - Good diquark: isospin 0 and spin 0
  - $\Lambda((ud)s)$  polarization comes from s
  - $\Xi(u/d(ss))$ , polarization comes from u/d?
- Purpose of studying  $\Xi$  polarization
  - Probe production mechanism (Hadronic/partonic)
  - Understand the origin of hyperon polarization

- $\Lambda$  polarization with circular polarized photon beam is consistent with 100%
- $\Sigma$  polarization does not have the same behavior  
(PRC75, 035205(2007))

# Existing Data(CLAS): $\Xi^-$ Induced Polarization in Photoproduction

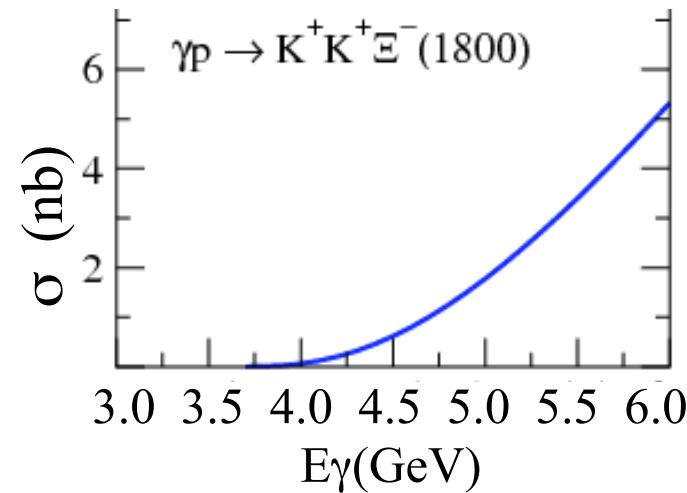

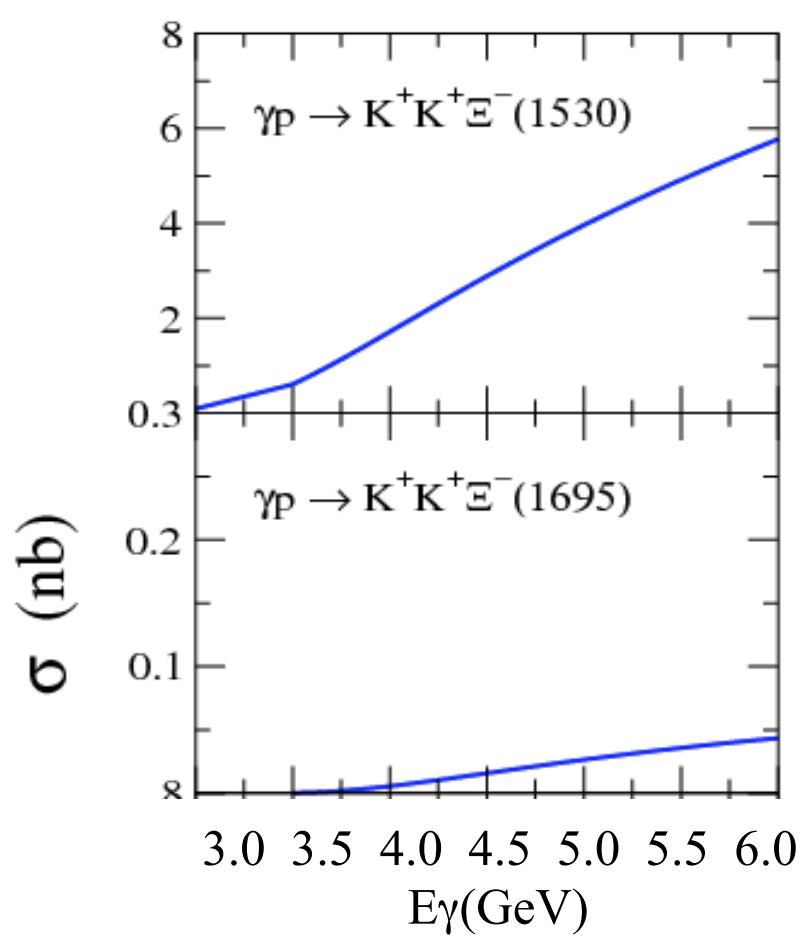

Existing data: No beam/target polarization

The only direction X can be polarized is out of plane  
(Parity conservation)

CLAS12 (with FT): polarization transfer for  $\Xi^-$   
 $P_\gamma$  known on an event by event basis

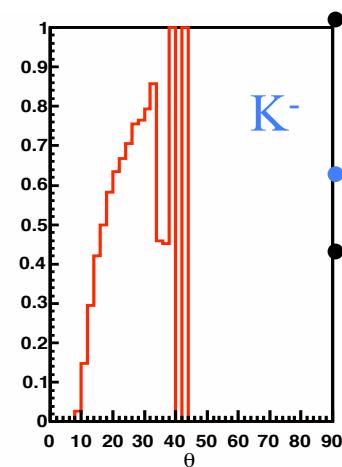

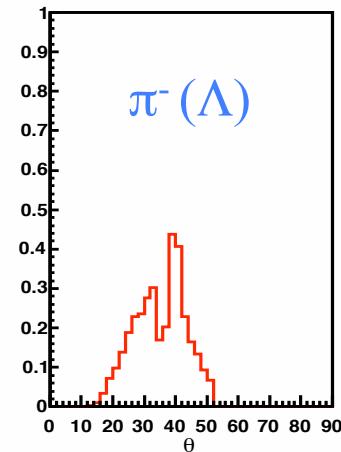

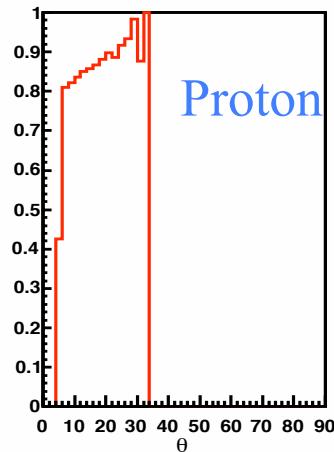

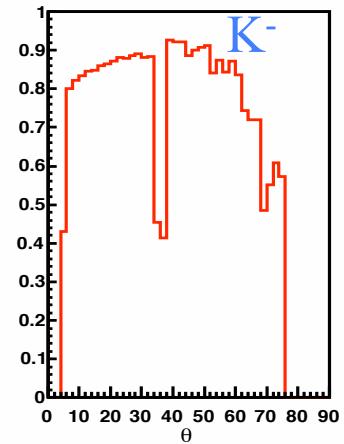

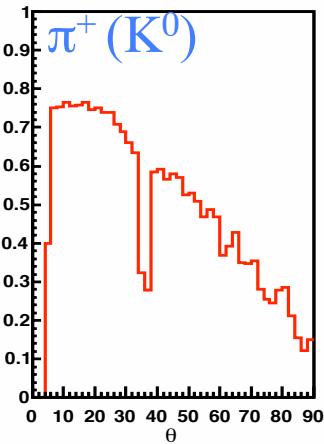

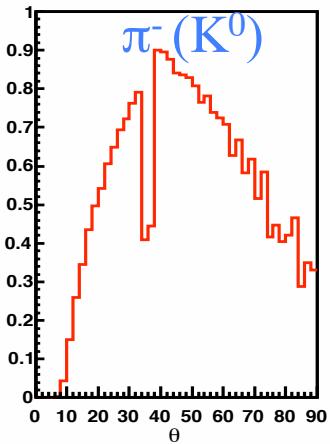

# Excited Cascade Production (Prediction)

K. Nakayama, Y. Oh, and H. Haberzettl  
results obtained using parameters  
obtained from PRC74, 032505(2006)  
Predictions for the  $\Xi(1820)$  IS consistent  
with CLAS data:  
signal would have been insignificant

# Simulation and Acceptance

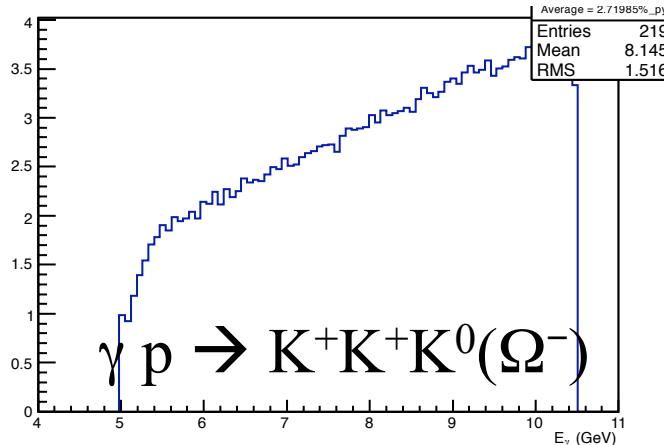

Acceptance

$\theta_{\text{lab}}$

- Reaction simulated  
 $\gamma p \rightarrow K^+ K^+ K^0 K^- (\Lambda)$   
 $K^0 \rightarrow \pi^+ \pi^-$   
 $\Lambda \rightarrow p \pi^-$
- The  $\pi^-$  (from  $\Lambda$ ) has the smallest acceptance  
Its detection is unnecessary  
**Half-field** is assumed  
Consistent with the meson-experiment requirement

# Impact of Full Field on Acceptance

## Topology

Topology	Half-field average Acceptance	Full-field average acceptance
----------	-------------------------------	-------------------------------

$K^+ K^+ K^0 (\Omega^-)$

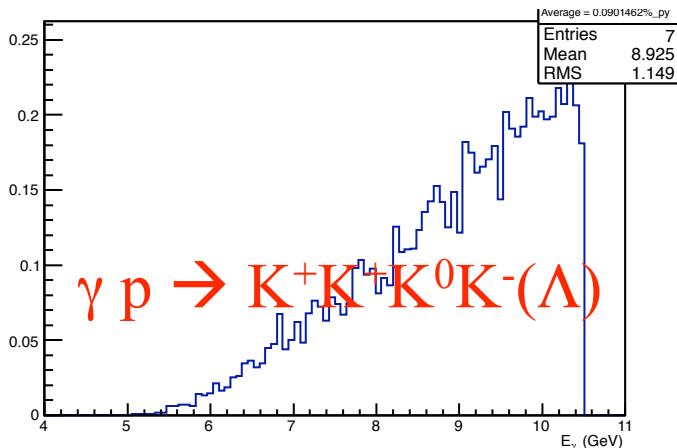

5.03%

2.72%

$K^+ K^+ K^0 K^- (\Lambda)$

0.76%

0.09%

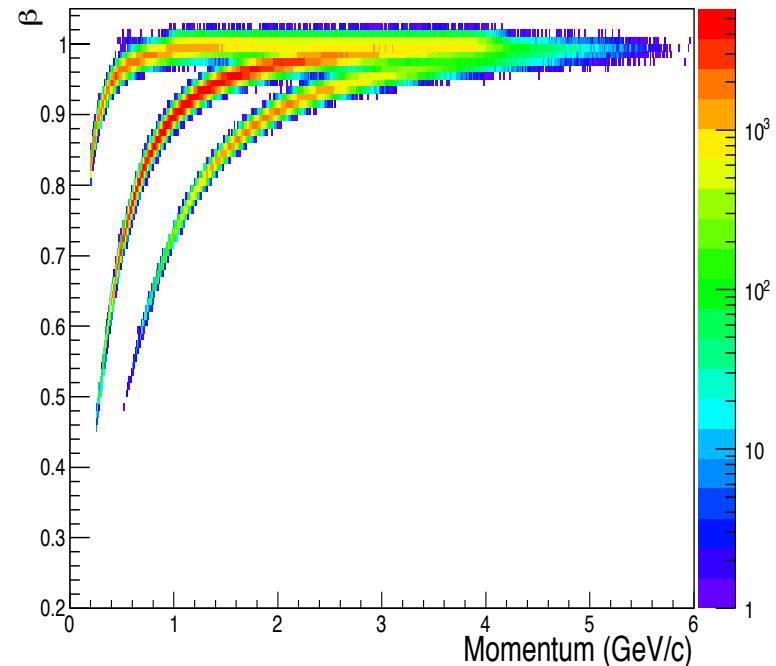

- 4-K channel for  $\Omega^-$  detection is impacted the most
- $\Xi$  channels are less affected due to higher statistics
- We need half field for the  $\Omega^-$  measurements

# Kinematic Coverage/PID

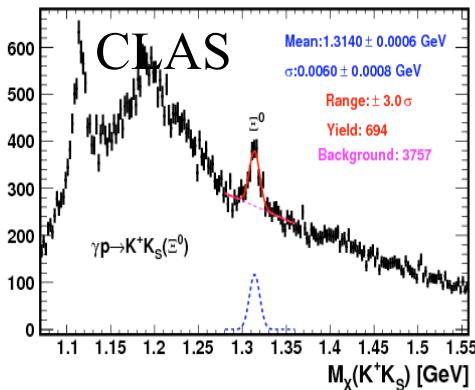

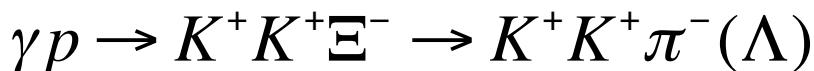

- Most of the multiples kaons in the final state have momenta lower than 2 GeV, where CLAS12 expects excellent K/ $\pi$  separation

Availability of a RICH detector Would be obviously very beneficial. Without it, we still expect excellent PID

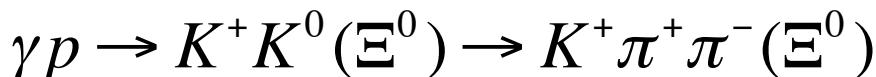

# Expected Results: Mass Splitting Measurements

- $\Xi^-$  Measurement:

- $\Xi^0$  Measurement

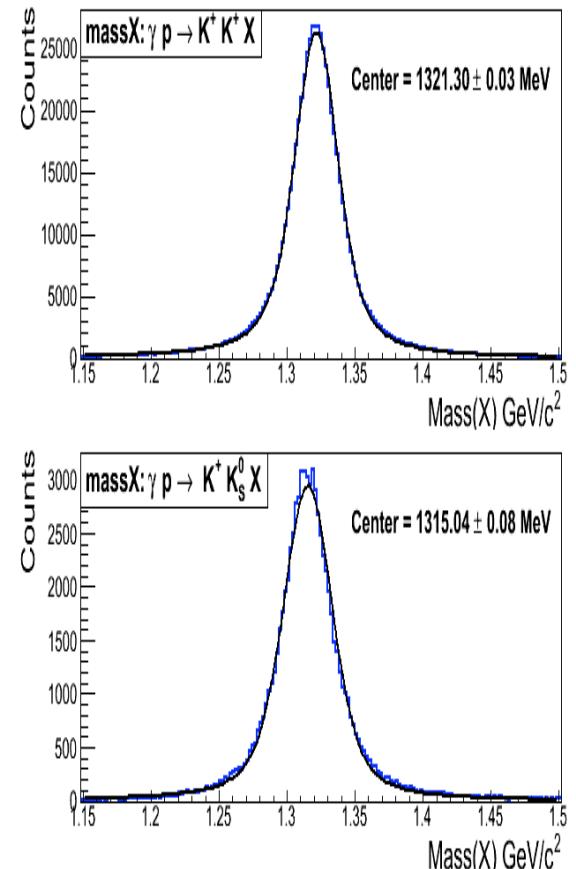

- Measurements feasible in multiple channels to reduce systematic uncertainty

Calibration can be tuned using other well known states ( $\Lambda$ ,  $\Sigma$ ,  $K_S$ , etc)

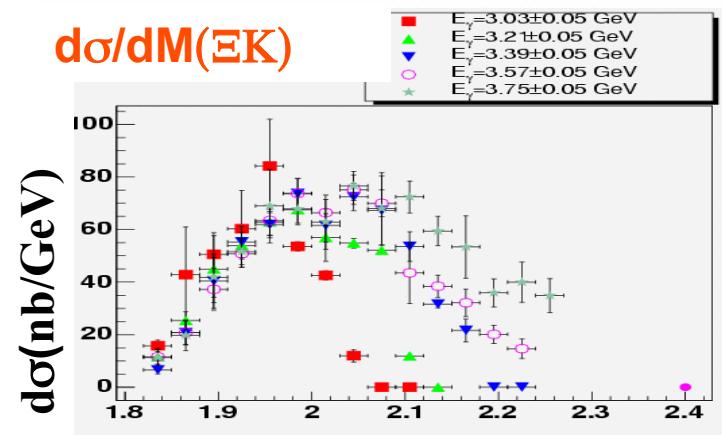

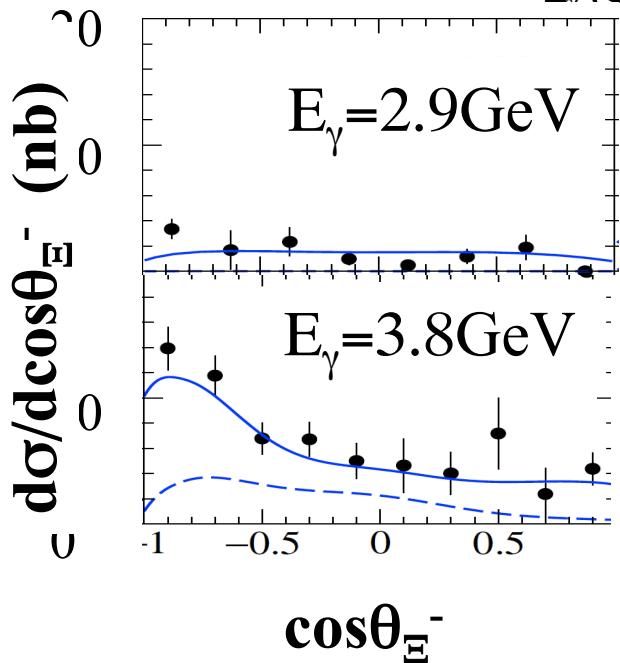

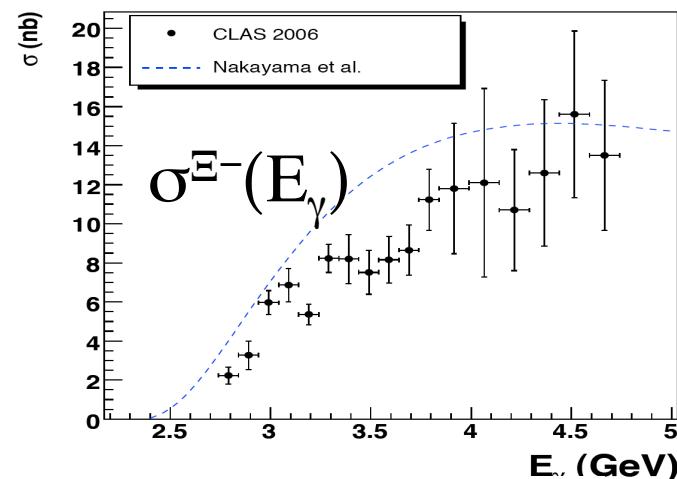

Expected statistical uncertainty:

$$\delta^{stat} (M_{\Xi^-} - M_{\Xi^0}) < 0.1 MeV$$

CLAS12/Simulation

# Energy Dependence of the $\Xi^-$ Cross Sections

- Nakayama et al. predicts plateauing behavior at higher beam energies  
[PRC 74, 035205 \(2006\)](#)  
[PRC83, 055201\(2011\)](#)
- Model only included limited number of intermediate hyperons
- The  $\Xi^-$  cross section could continue to increase at higher  $E_\gamma$
- Angular distributions expected to change with  $E_\gamma$
