

# Search for heavy photons at JLab

Rafayel Paremuzyan

University of New Hampshire

Correlations in Hadronic and Partonic interactions

Yerevan, Sept. 24-28

# The Continuous Electron Beam Accelerator Facility

# The Dark Photon $A'$

What, if Nature contains an additional broken U(1) (Abelian) force mediated by a massive vector boson,  $A'$ ? Bob Holdom, Phys.Lett.,B166, 2, (1986)

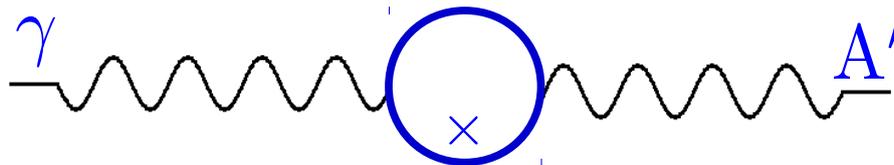

$$\mathcal{L} = \mathcal{L}_{SM} + \frac{\epsilon}{2} F^{Y,\mu\nu} F'_{\mu\nu} + \frac{1}{4} F'^{\mu\nu} F'_{\mu\nu} + m_{A'}^2 A'^{\mu} A'_{\mu}$$

Kinetic Mixing Induces weak coupling to electric charge

$\epsilon$  is the mixing strength

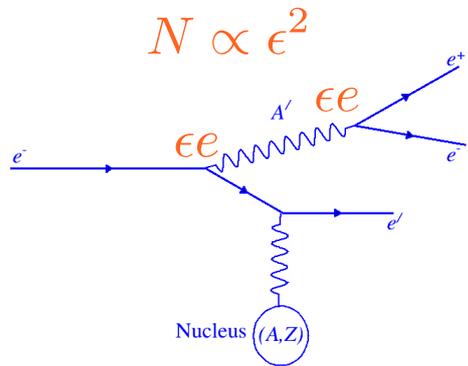

generated by heavy particles  
× interacting with  $\gamma$  and  $A'$

# Where can A's be produced

Where there are photons, there can be dark photons:

Electrons on fixed target

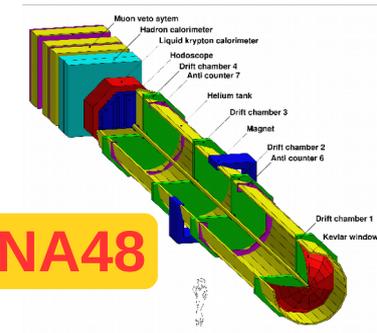

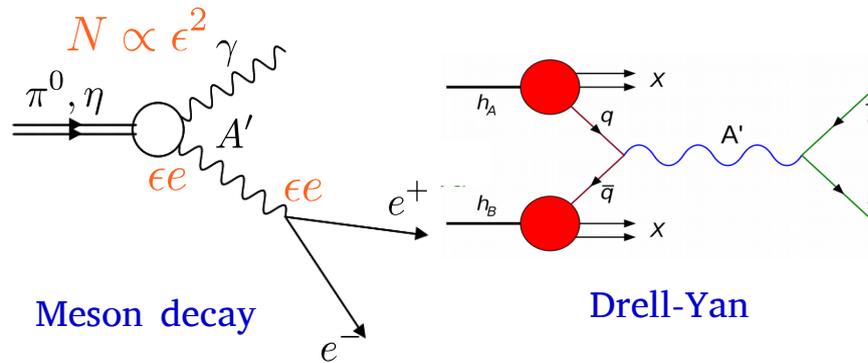

A' Strahlung

**APEX**

**DARKLIGHT**

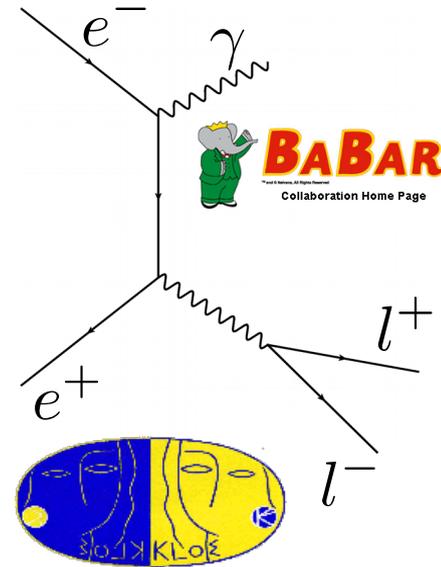

Protons on fixed target

**NA48**

**SeaQuest E906**

$e^-e^+$  colliders

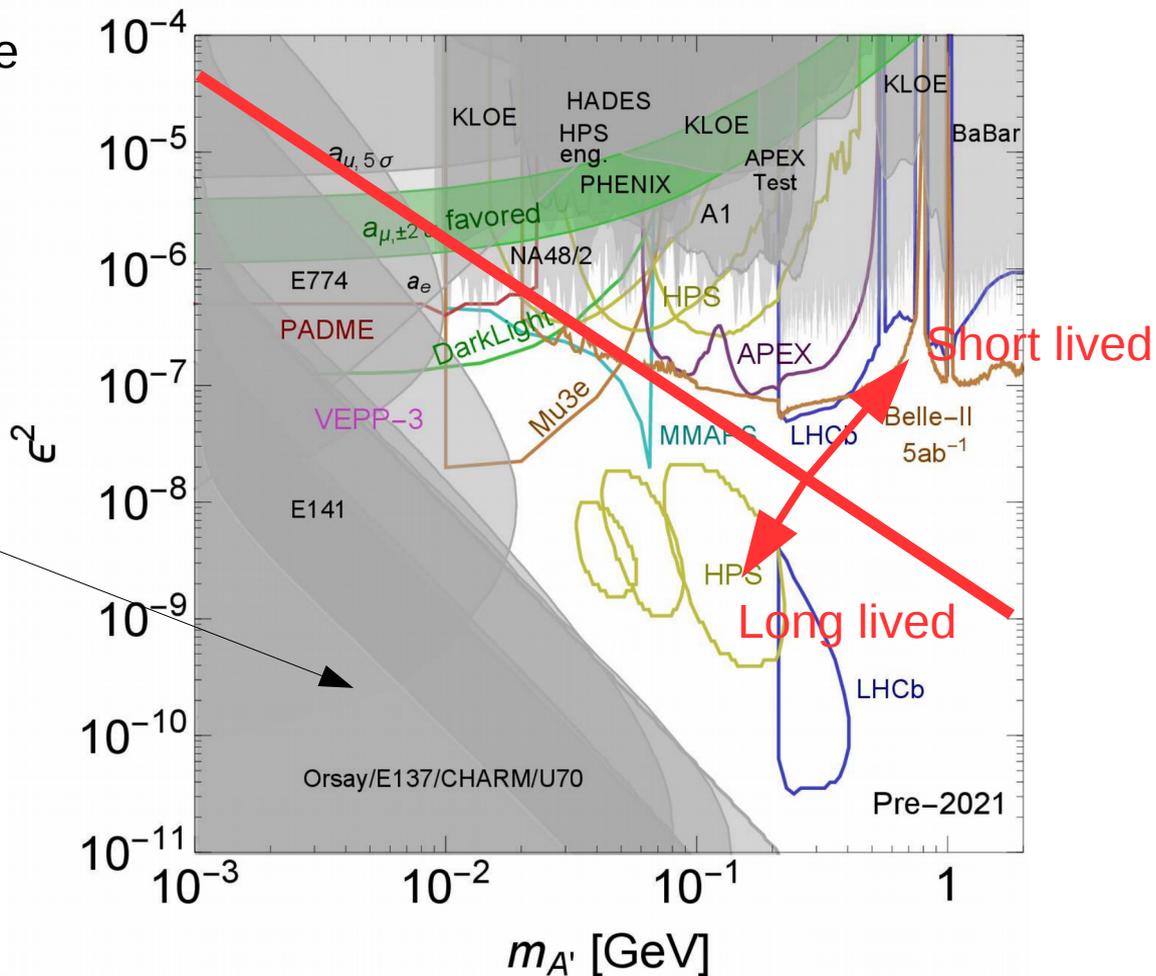

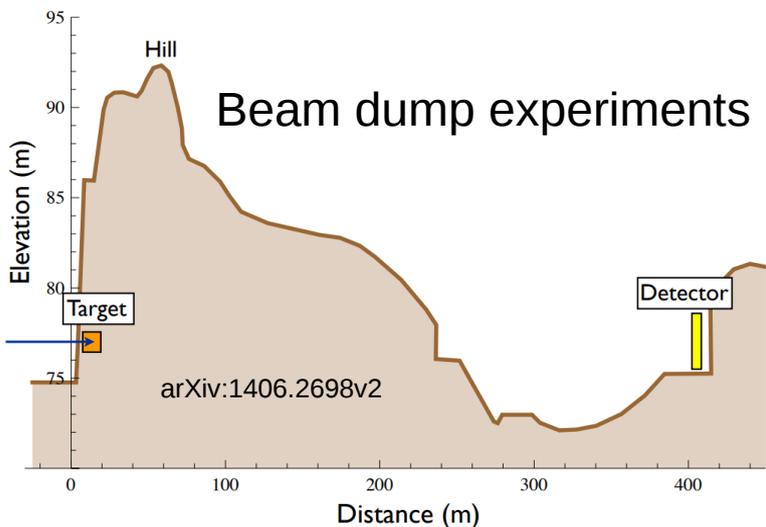

$e^-e^+ \rightarrow A'\gamma$   
Meson decay

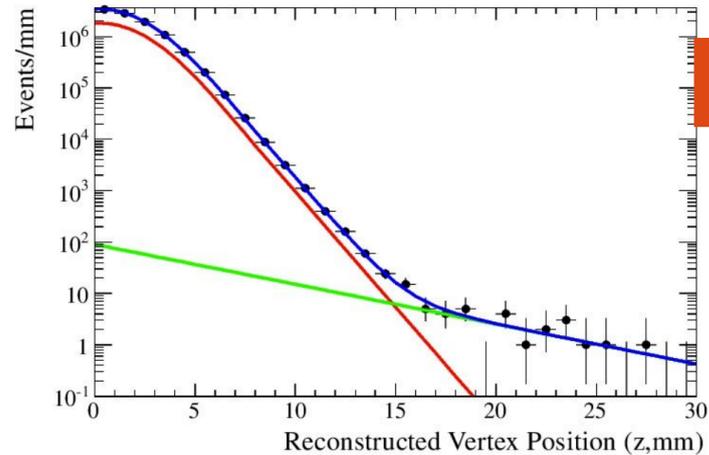

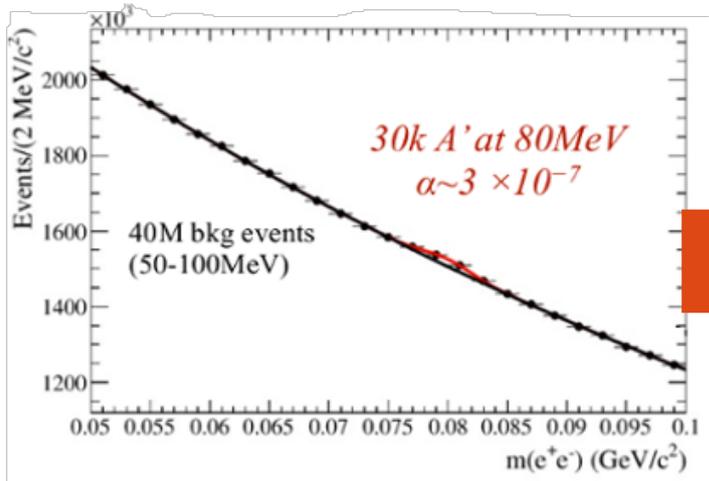

# Existing and projected constraints on $A'$

Most of the constraints come from the “bump hunt” searches looking for a resonance in the  $e^-e^+$  mass spectrum

$$l_0 \equiv \gamma_{CT} \propto \frac{1}{\epsilon^2 m_{A'}^2}$$

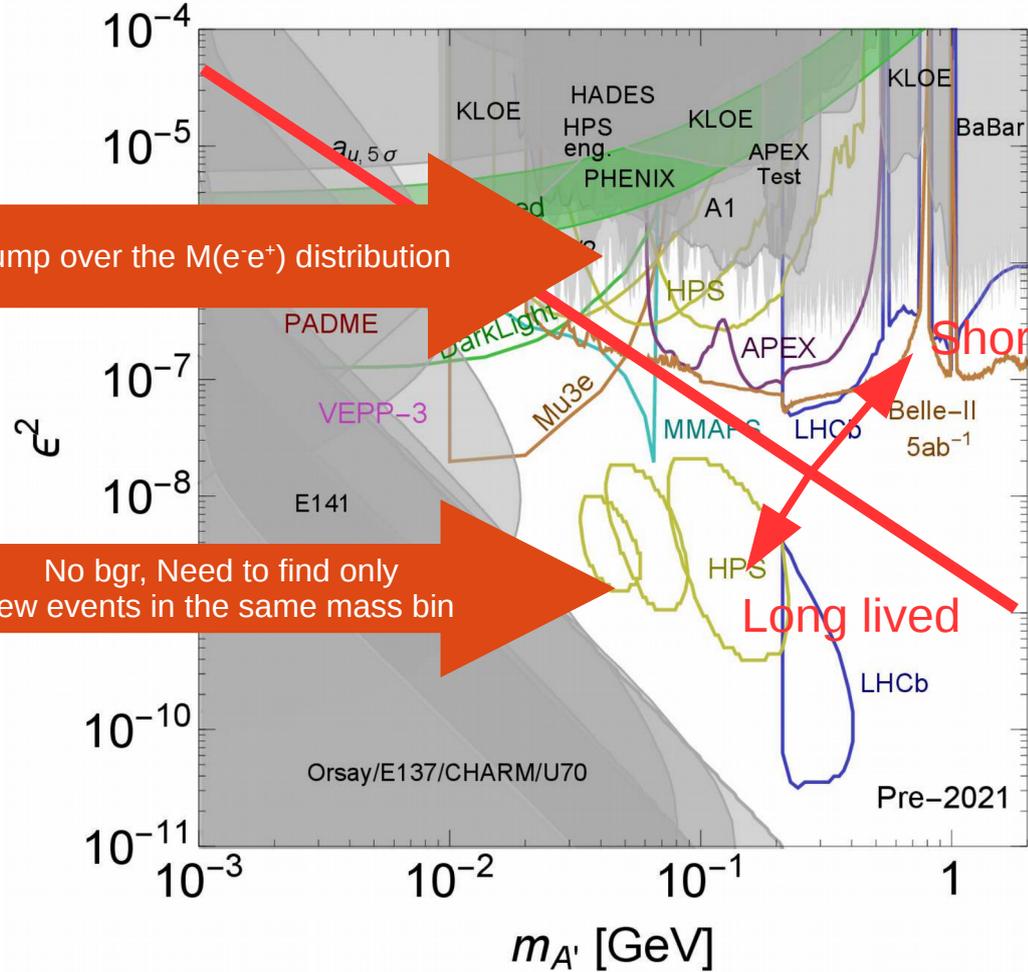

# Existing and projected constraints on $A'$

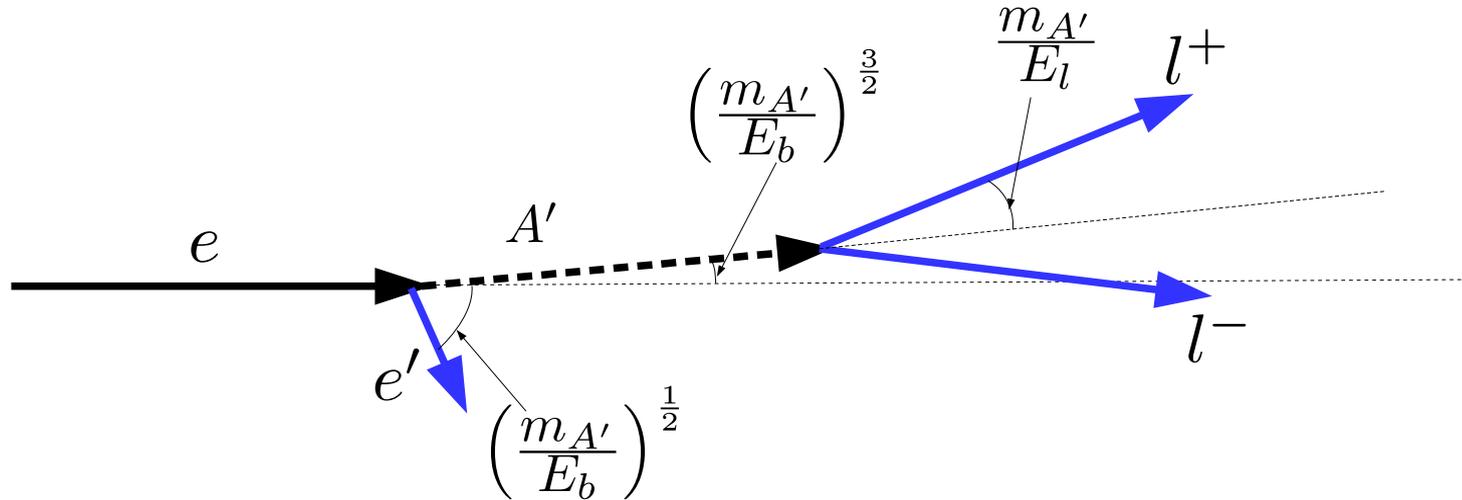

Bump over the  $M(ee^+)$  distribution

No bgr, Need to find only few events in the same mass bin

# Heavy photon kinematics on fixed target experiments

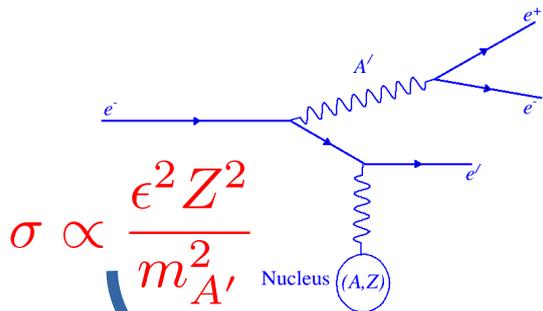

- \* Unlike Bremsstrahlung  $A'$  takes almost all the beam energy
- \* Peaked at forward angles

- Fixed target experiments are therefore designed to be sensitive to small angles
- Maximize acceptance for high  $E_{\text{sum}}$ .

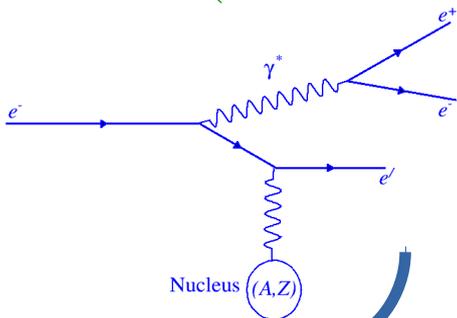

# Background process in $A'$ production w/ e- beam of fix target

$A'$  production

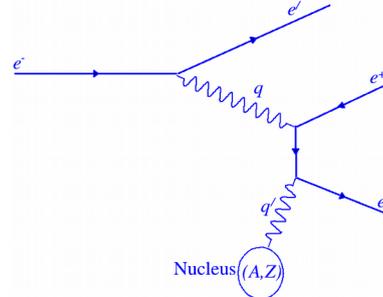

$$\sigma \propto \frac{\epsilon^2 Z^2}{m_{A'}^2}$$

Production of Timelike photon (radiative Tridents)

Bethe Heitler

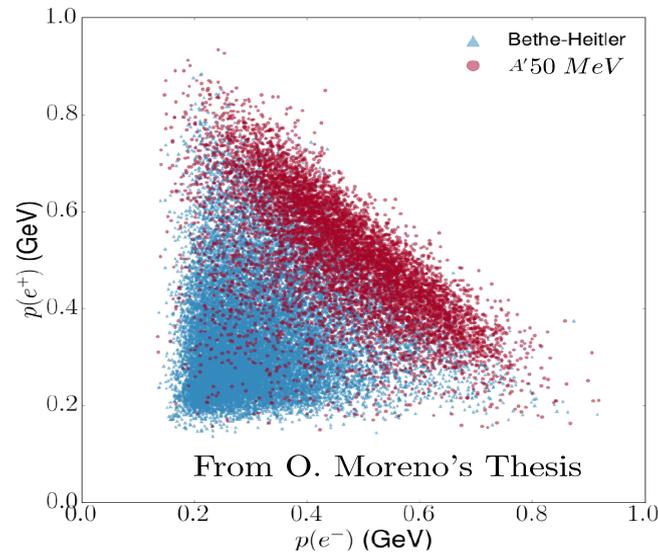

Much larger cross section, But very different kinematic

Similar kinematics for fixed  $M(e^-e^+)$

$$\frac{\sigma(eA \rightarrow e'A'(\rightarrow e^-e^+))}{\sigma(eA \rightarrow e'\gamma^*(\rightarrow e^-e^+))} = \left( \frac{3\pi\epsilon^2}{2N_f\alpha} \right) \frac{m_{A'}}{\delta m} \leftarrow \text{Mass bin}$$

Known QED process =>  $\epsilon$  can be calculated by above ratio

It is critical to have a good mass resolution

# Experiments at JLab

APEX in Hall-A

HPS in Hall-B

DarkLight in LERF (FEL)

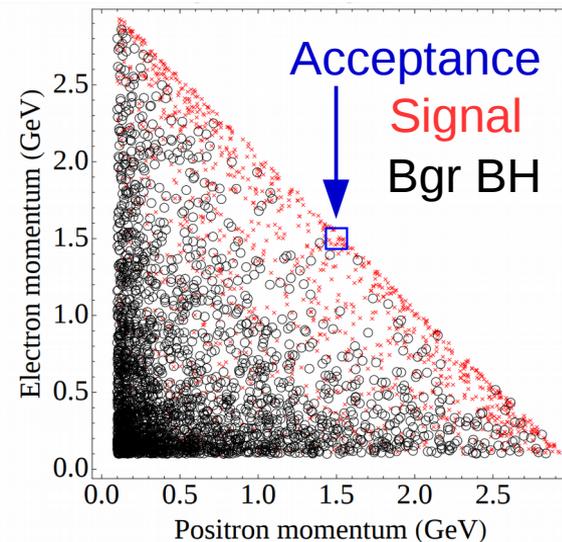

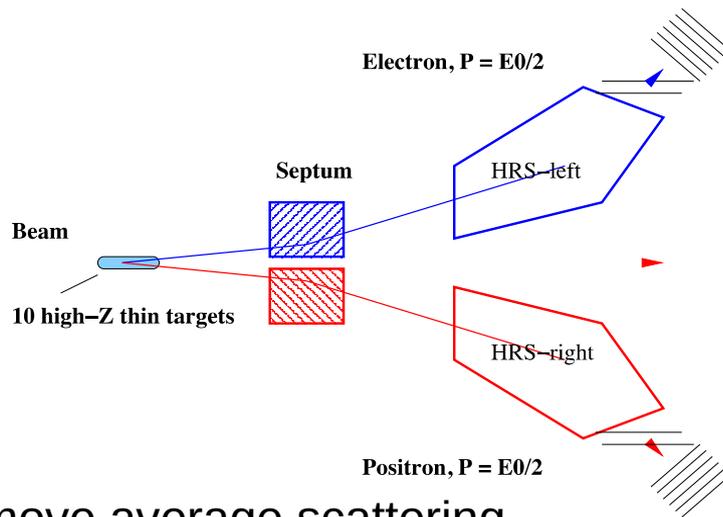

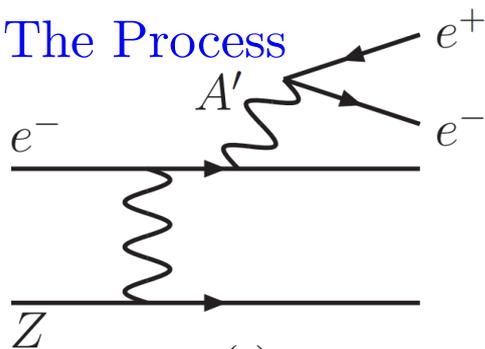

BDX, new underground facility  
Behind the Hall-A dump

# A Prime Experiment

## The Process

\*Septum magnet allows to move average scattering angles from  $12^\circ$  to  $5^\circ$ .

\*Momentum Acc:  $P_0 \sim 9\%$ ,

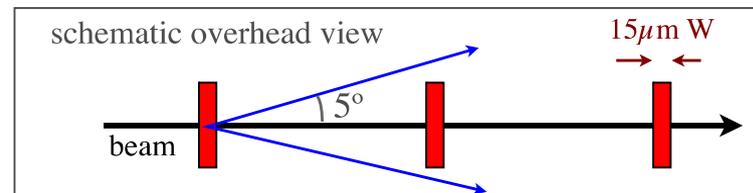

\* $e^-$  and  $e^+$  have symmetric acceptance  $P \approx 0.5 \cdot E_{\text{beam}}$ .

\*Momentum resolution is below  $1 \cdot 10^{-3}$ .

\*  $\delta\theta = 0.5 \text{ mrad}$   $\delta\phi = 1 \text{ mrad}$

\*Multi-foil targets: increase the mass range and reduce the multiple scattering

- $\sigma(\theta)_{\text{mult scat}} \leq 0.5 \text{ mrad}$   
 $\Rightarrow$  typical  $e^+e^-$  pair must only go through  $0.3\% X_0$  (2-pass)
- Target thickness  $0.7\text{--}8\% X_0$  (depending on  $E_{\text{beam}}$ )

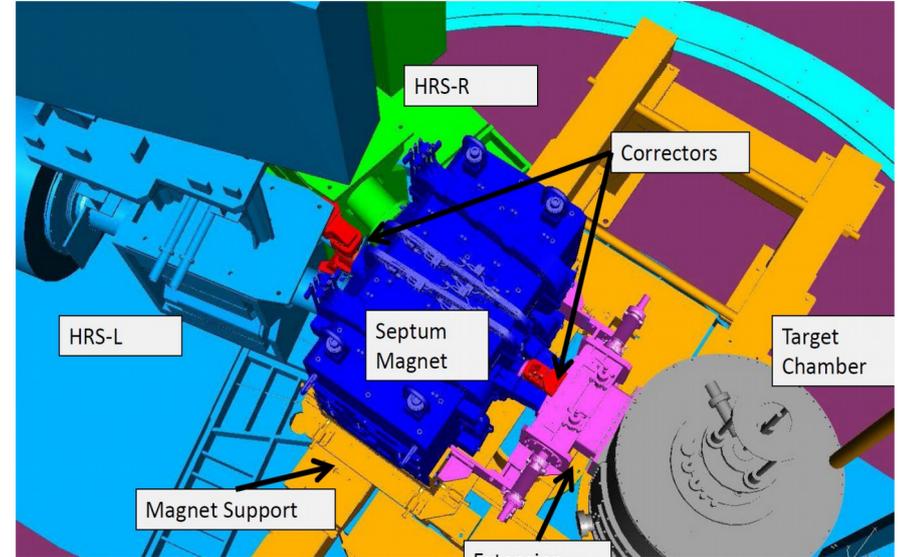

- High-Z target (reduce  $\pi$  yield for given QED rates)
- Stable under currents up to  $\sim 100 \mu\text{A}$

# Detector components

## High resolution spectrometers

## Whole assembly, from top

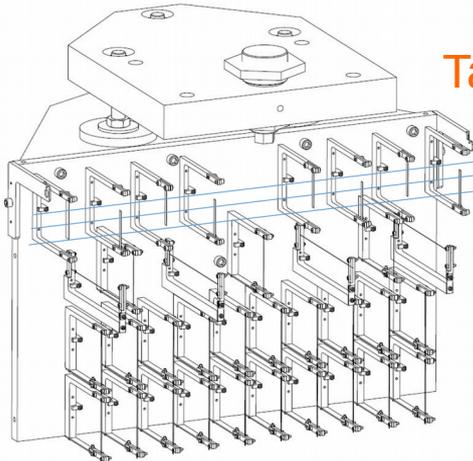

## Target

Calibration of magnetic optics

10 Graphite foils, tot 0.07% RL

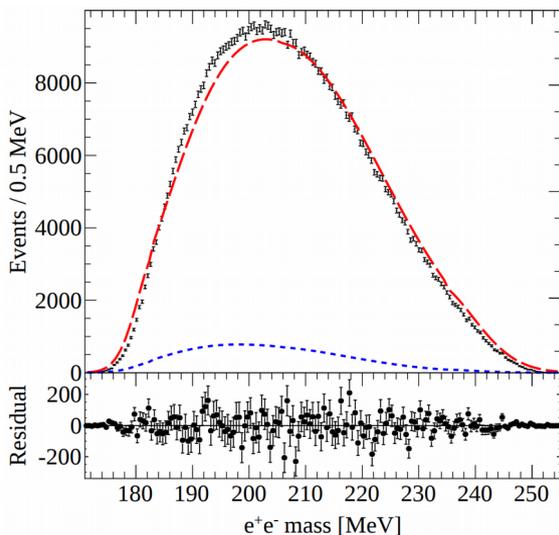

10 Tungsten foils, 2.8% RL

Electrons will be detected in HRS-L,  
while positrons in HRS-R

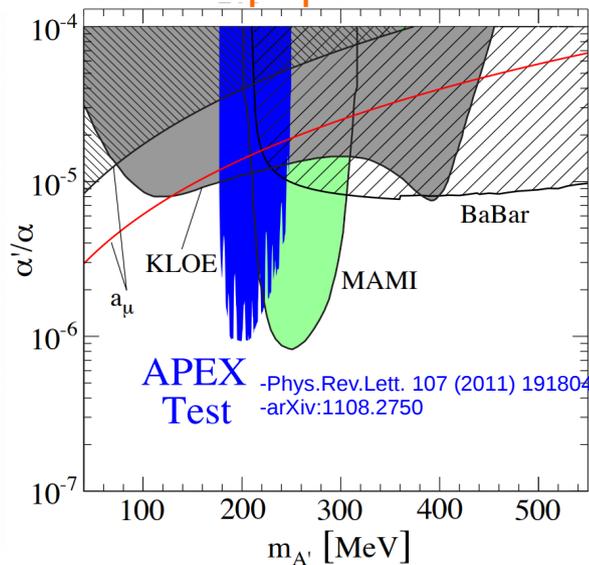

# Test run and expected reach

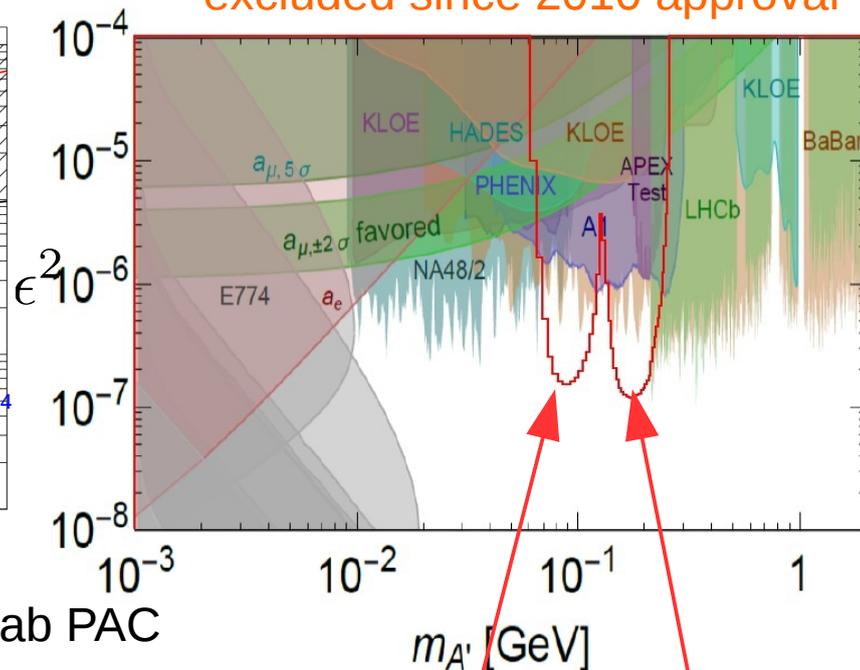

APEX test run

Territory at the time of test run paper

Significant territory is already excluded since 2010 approval

APEX is classified as a high impact experiment by JLab PAC

Next run: Jan 30 - March 10, 2019 with 2.1 GeV beam

Beam current up to 120  $\mu$ A

Luminosity  $10^{39}$   $\text{cm}^{-2}$   $\text{s}^{-1}$ .

15 days at 2.2 GeV  
15 days at 1.1 GeV

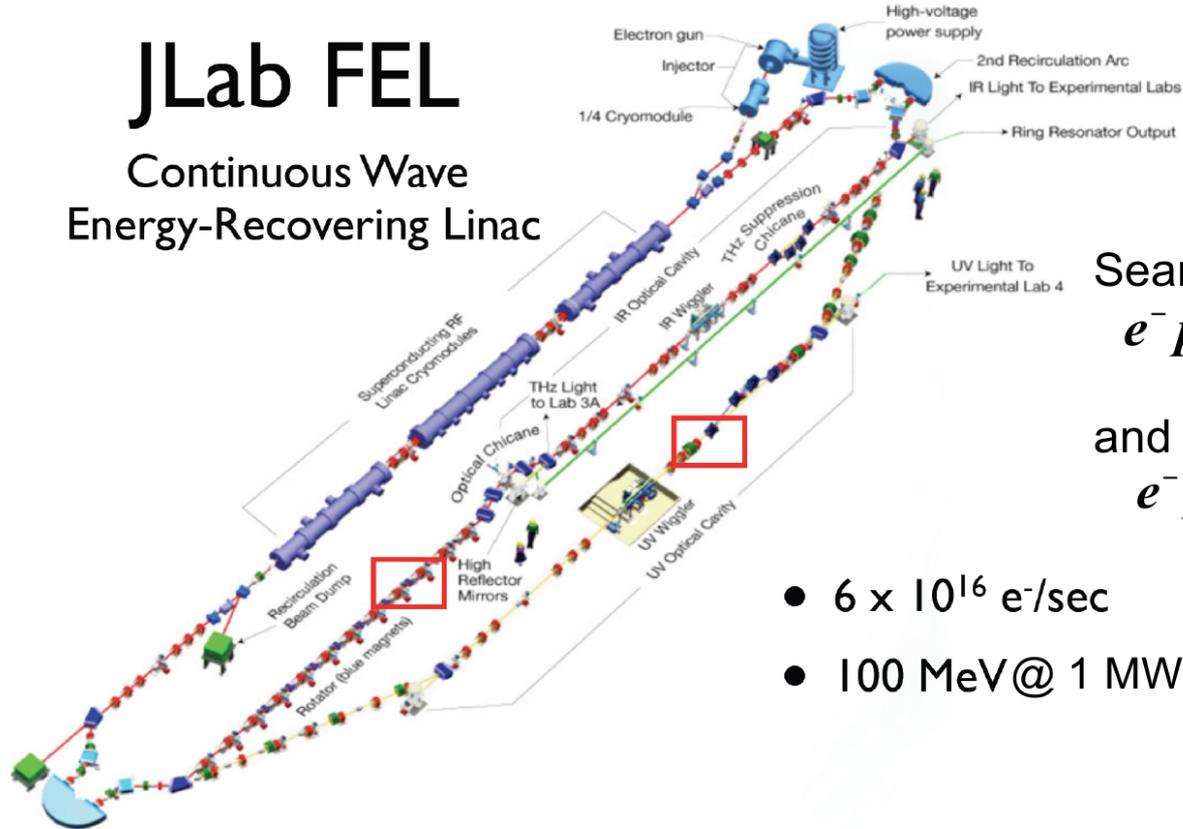

High resolution, high luminosity experiment!

# Electron scattering of hydrogen gas target

## JLab FEL

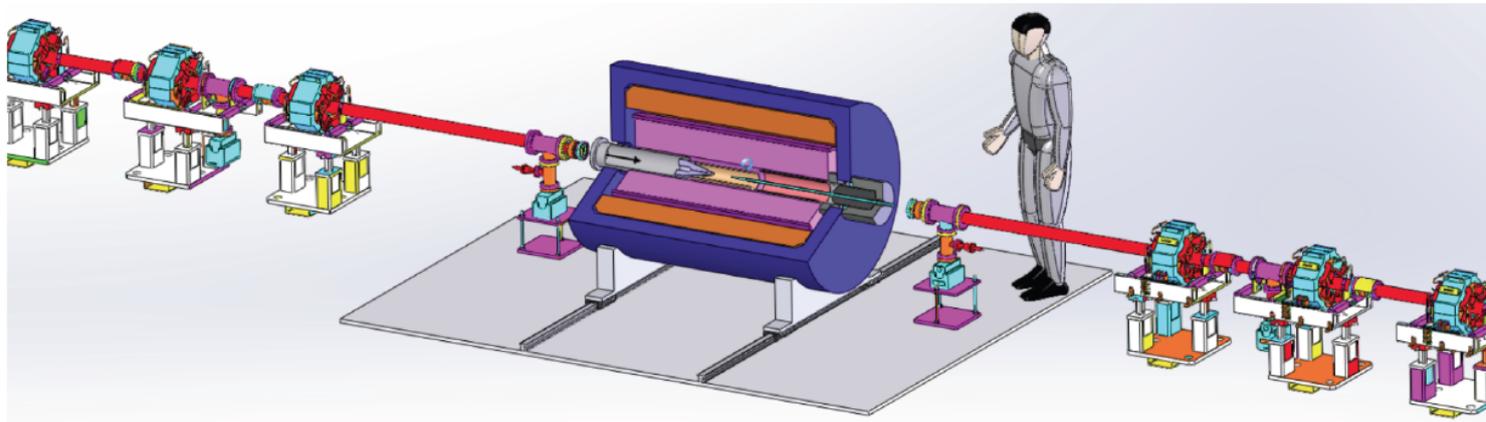

Continuous Wave  
Energy-Recovering Linac

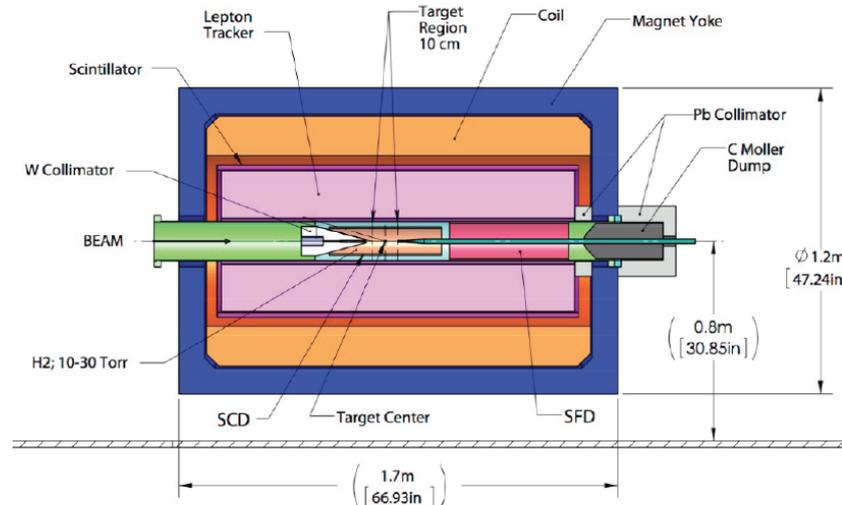

Search for  $A'$  in “visible”  
 $e^- p \rightarrow e^- p A', A' \rightarrow e^+ e^-$

and “invisible” decay modes  
 $e^- p \rightarrow e^- p A', A' \rightarrow inv.$

- $6 \times 10^{16}$  e<sup>-</sup>/sec
- 100 MeV @ 1 MW

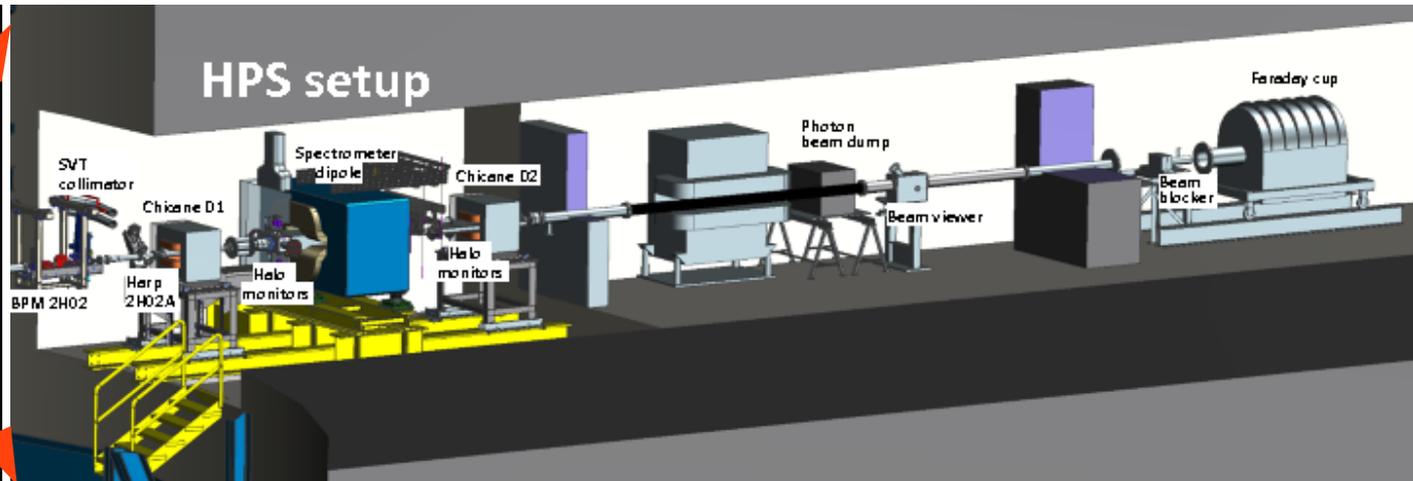

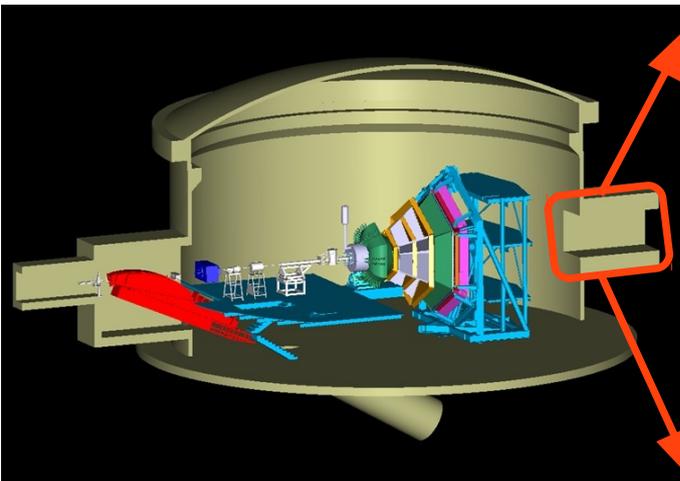

- Windowless target, aggressively pumped
- Gas thickness  $\sim 10^{19} \text{cm}^{-2}$  with 10mA beam yields  $\sim 0.5 \text{ ab}^{-1}/\text{month}$
- Thin beryllium beam pipe
- Si detector for proton recoil
- TPC + 0.5 T magnet
  - High track density
  - $\sim 250 \mu\text{m}$  hit res.
  - Magnet confines low- $p_T$  backgrounds (e-p and Moller)
- Scintillators serves as veto for invisibles search

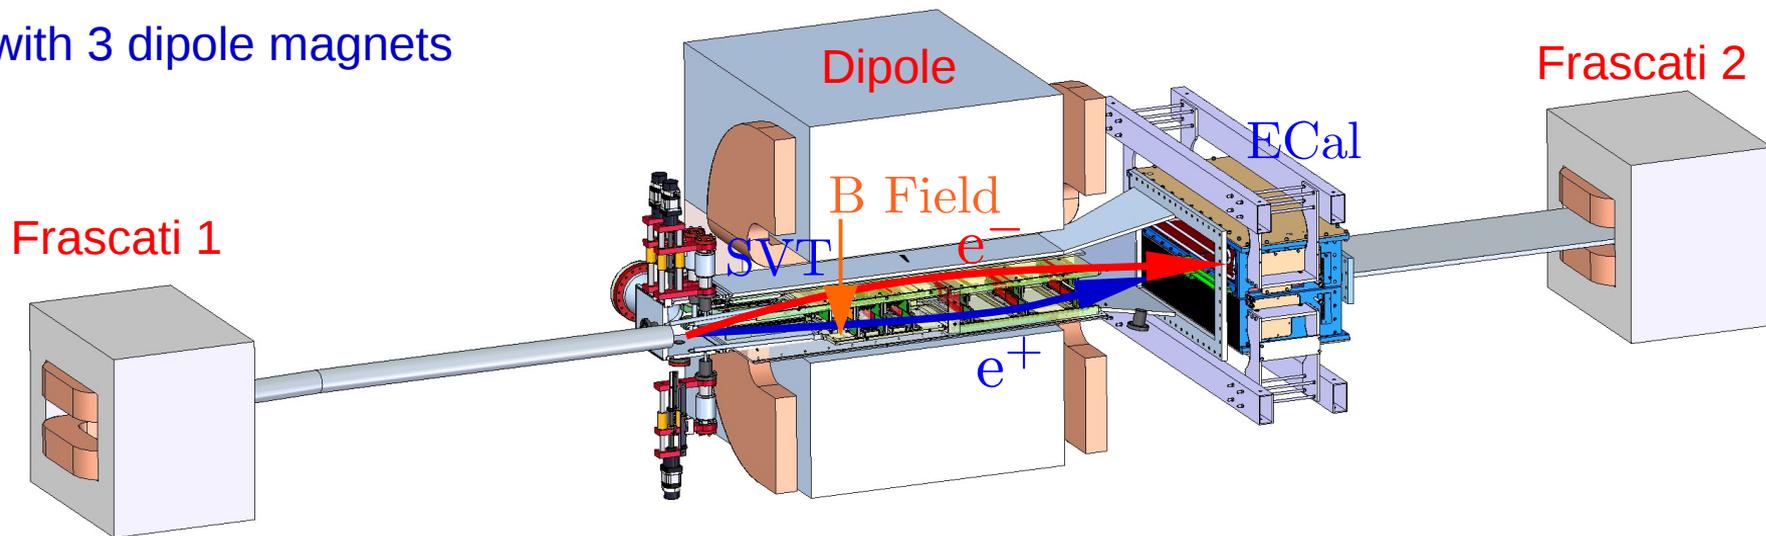

# Hall-B

# Hall-B Alcove

Chicane with 3 dipole magnets

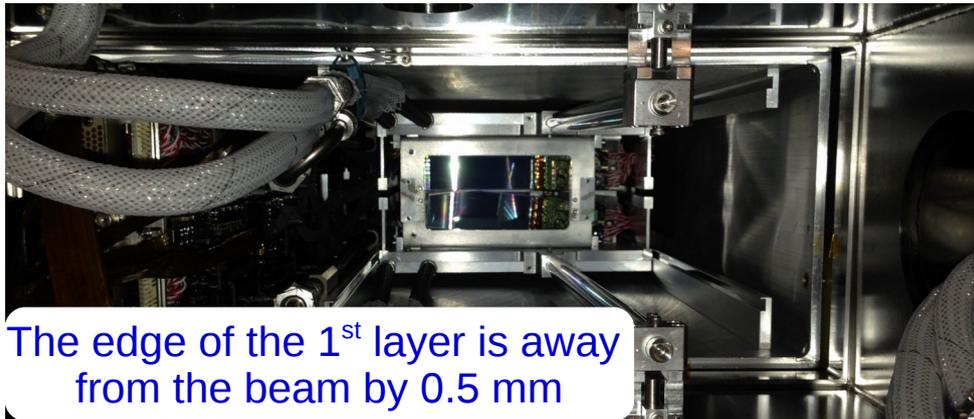

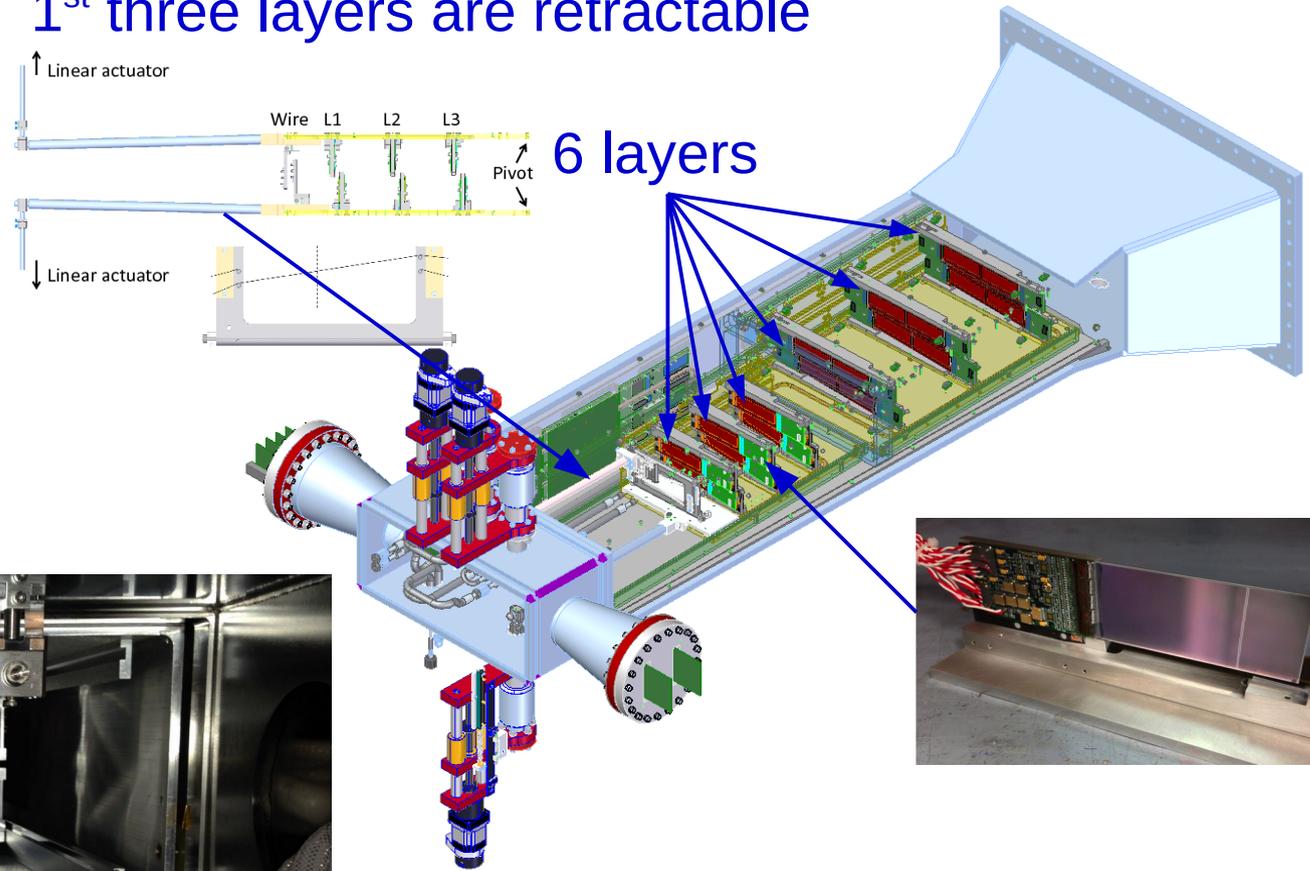

# Silicon Vertex Tracker

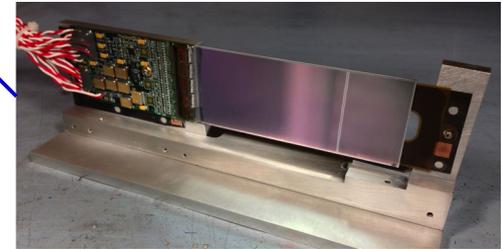

1<sup>st</sup> three layers are retractable

Each layer consists of two sensors stereo and axial

Layers 1-3 single sensor  
Layers 4-6 double sensors

The edge of the 1<sup>st</sup> layer is away from the beam by 0.5 mm

# Electromagnetic Calorimeter

A homogeneous calorimeter made of 442 (221 per sector) lead tungstate ( $\text{PbWO}_4$ ) crystals readout with  $10 \times 10 \text{ mm}^2$  APDs.

Crystal:  $13.3 \times 13.3 \text{ mm}^2$  front face

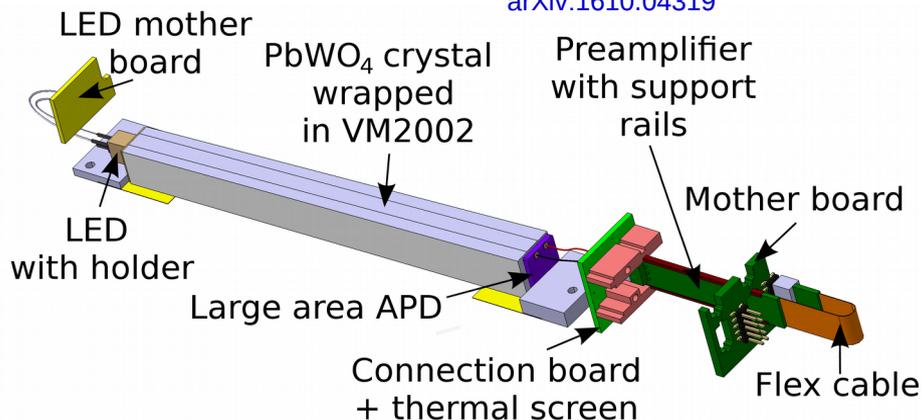

160 mm long (18 rad length)

In both sectors, 9 “Very HOT” crystals are removed from the 1<sup>st</sup> row

Signals are readout through 250 MHz fADC boards

FADC demonstrated pretty good time resolution, and after the 1<sup>st</sup> engineering run TDCs were removed

Nucl.Instrum.Meth. A854 (2017) 89-99  
arXiv:1610.04319

# The trigger

The trigger logic works based on ADC value and time of EC signals.

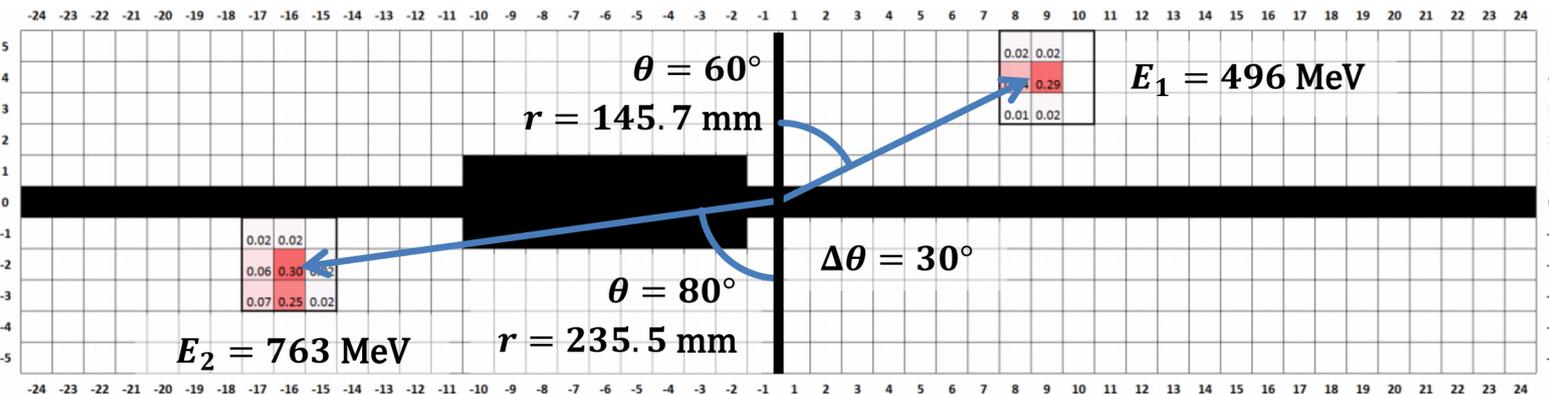

CTP performs cluster finding (collection of 3x3 hits within 12 ns time interval) then clusters are sent to SSP which searches for time coincidence of pairs of clusters from top and bottom halves and applies topological cuts.

$N_{\text{hits}} > \text{threshold}$   
 $E_{\text{min}} < E_{\text{clust}} < E_{\text{max}}$

Two types of triggers  
singles and pairs.

$N_{\text{hits}} > \text{threshold}$   
 $E_{\text{min}} < E_{\text{clust}} < E_{\text{max}}$   
 $E_{\text{sum\_min}} < E_{\text{sum}} < E_{\text{sum\_max}}$   
 $|\text{Coplanarity}| < \text{coplan\_max}$   
 $E > E_{\text{min}} + \text{slope} * d$

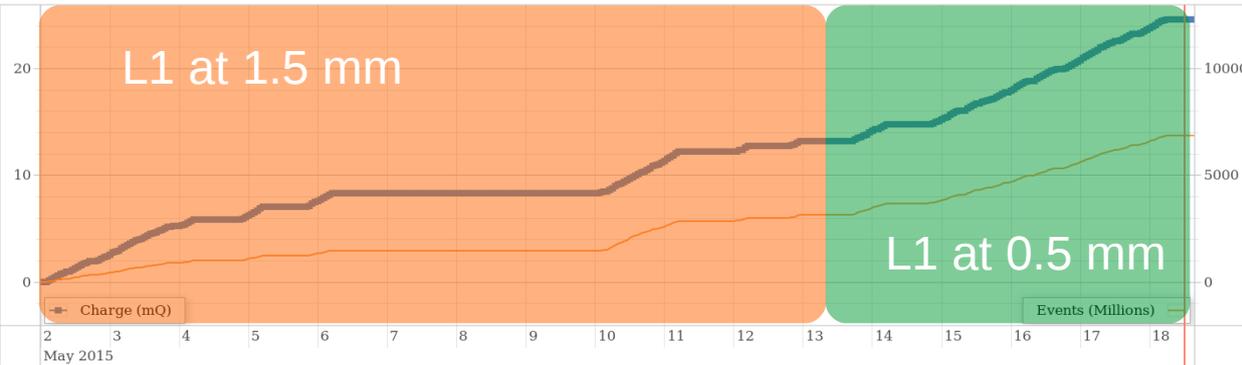

The production trigger: **pair1 trigger**, cut parameters are optimized for high energy  $e^- e^+$  pairs in opposite detector halves

# 2015 and 2016 Engineering runs

Opportunistic runs: to understand the performance of the detector and take physics data

Because of the CLAS12 construction work, HPS run on non-Business hours.

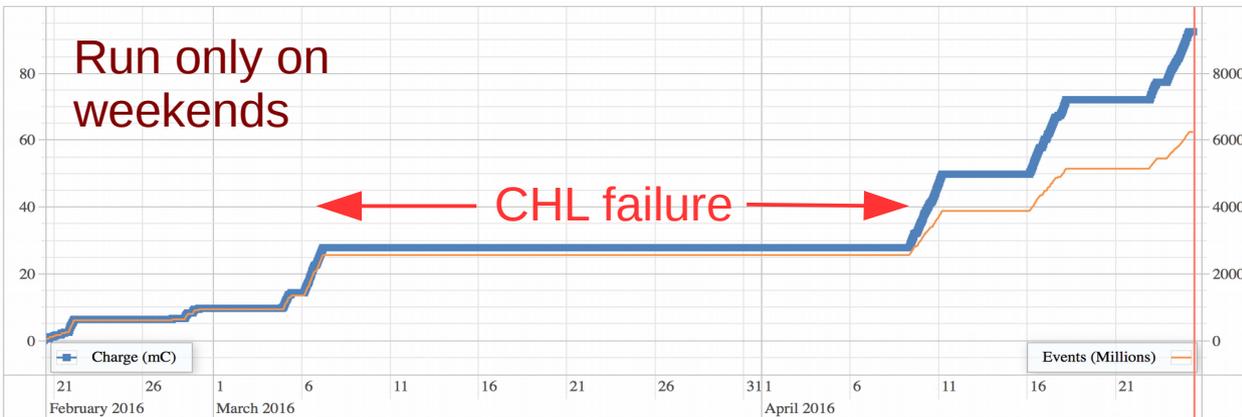

Spring 2015: 1.05 GeV @ 50 nA

10 mC with L1 at 1.5 mm

10 mC with L1 at 0.5 mm (design)

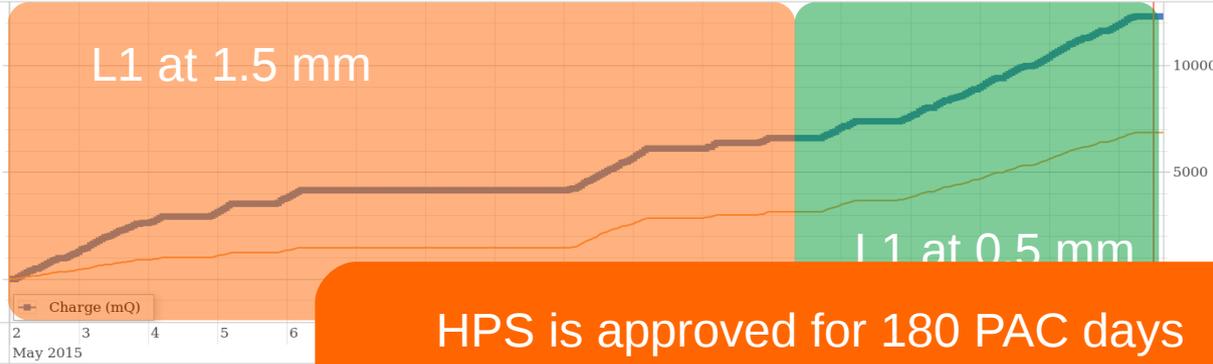

1.5 PAC days with L1 at 0.5mm

# 2015 and 2016 Engineering runs

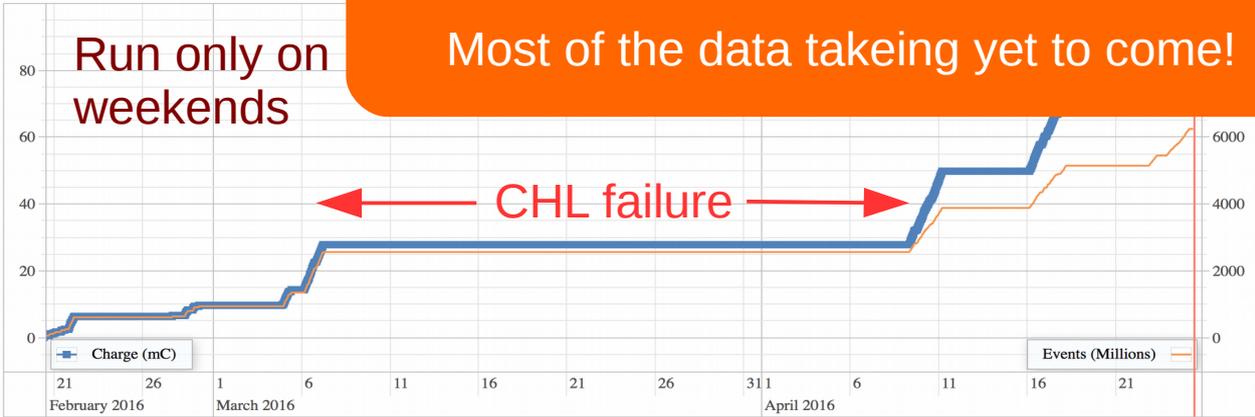

Opportunistic runs: to understand the performance of the detector and take physics data

Because of the CLAS12 construction work, HPS run on non-Business hours.

HPS is approved for 180 PAC days  
Most of the data taking yet to come!

Spring 2015: 1.05 GeV @ 50 nA  
10 mC with L1 at 1.5 mm  
10 mC with L1 at 0.5 mm (design)  
5 PAC days with L1 at 0.5mm

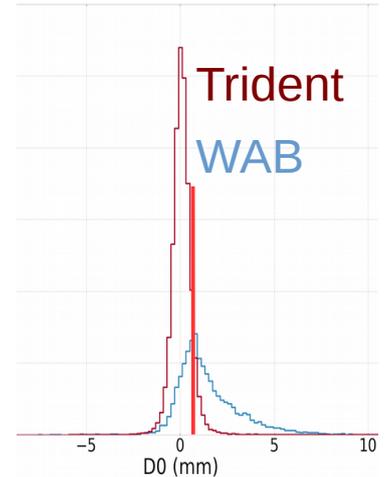

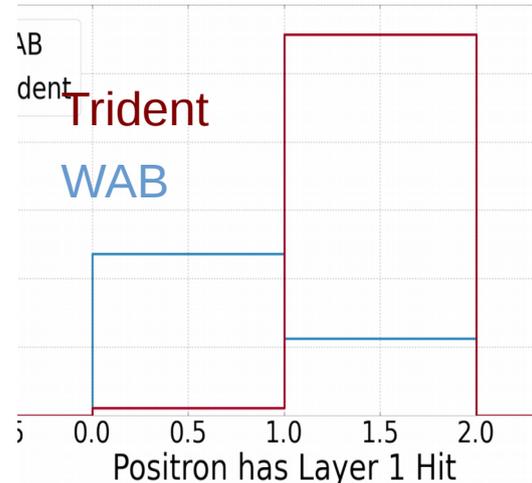

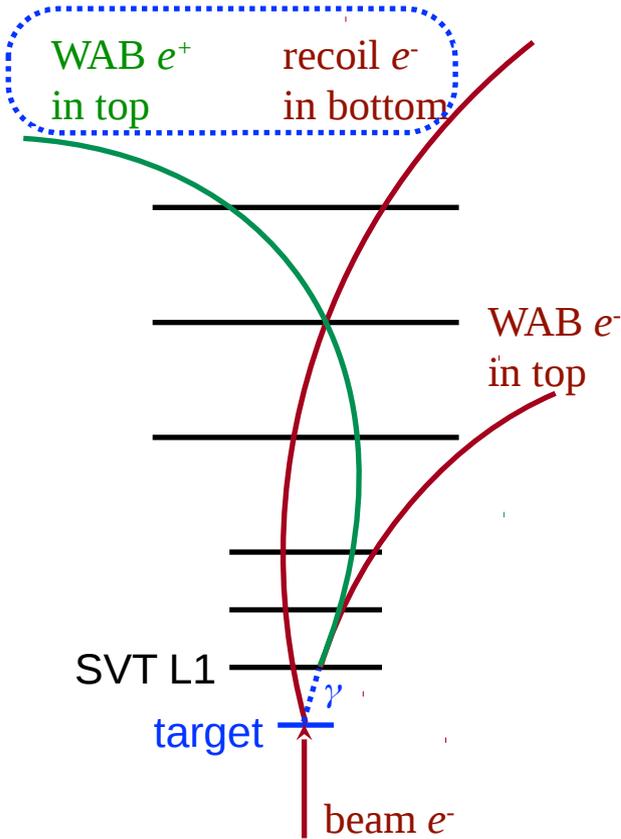

Spring 2016: 2.3 GeV @ 200 nA  
92.5 mC 5.4 PAC days  
L1 at 0.5 mm during the data taking

# Wide Angle Bremsstrahlung and pair conversion

During the analysis we realized that in the final state there is a significant contribution from the two step process: WAB → conversion in SVT layers

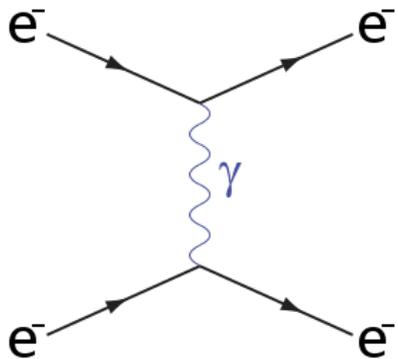

Cuts: requirement hit in L1 and d0 removes 80% of these events, without significant loose of tridents

EGS5 doesn't properly simulate electron scattering angle in WABs, and therefore these events didn't show up in the studies of the proposal

# Mass resolution

Good understanding of the mass resolution is a critical component in the “Bump Hunt” analysis

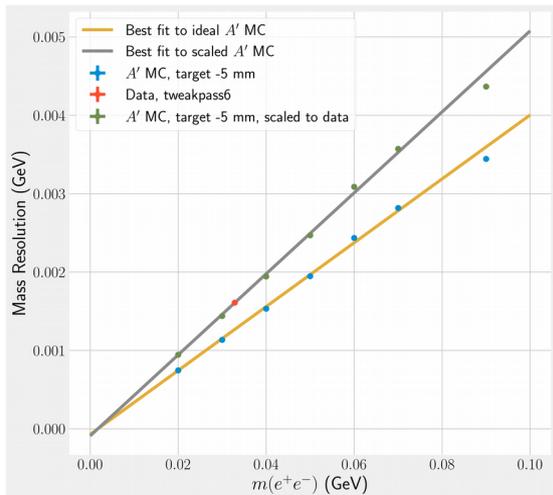

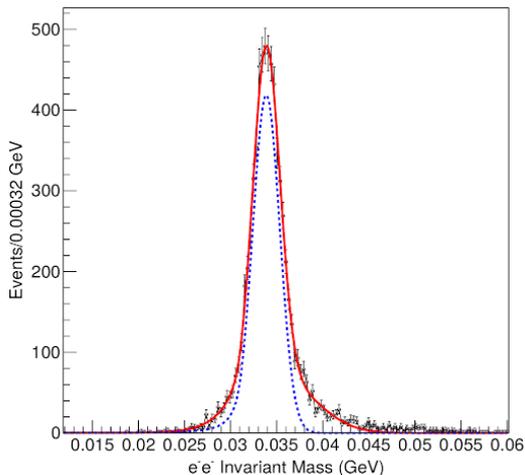

$$M(ee) \equiv \sqrt{2 \cdot E_b \cdot m_e} = 32.7 \text{ MeV}$$

We know the mass resolution of the data in a single point, Moeller mass.

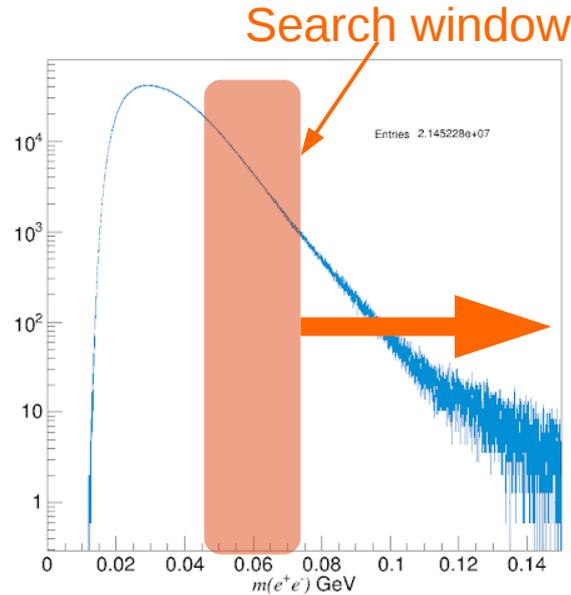

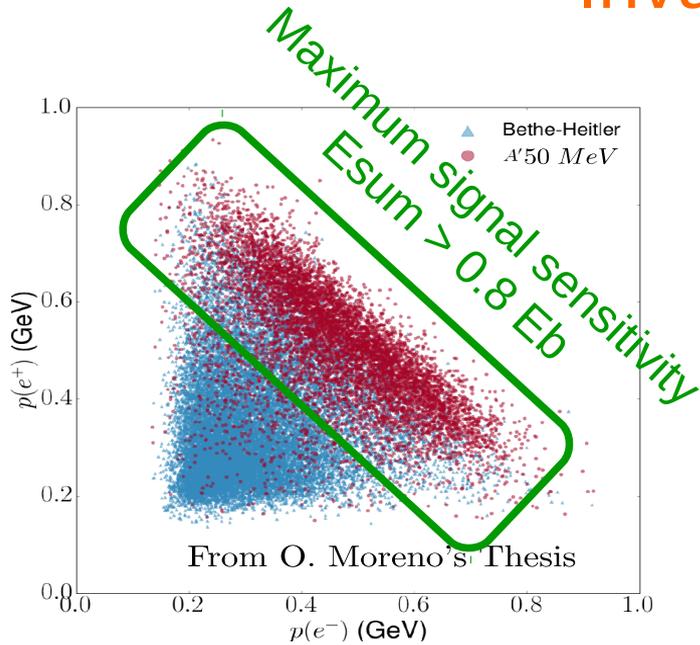

We have to rely on the Monte Carlo mass resolution for all other mass

Moeller process allows to check/calibrate the mass resolution

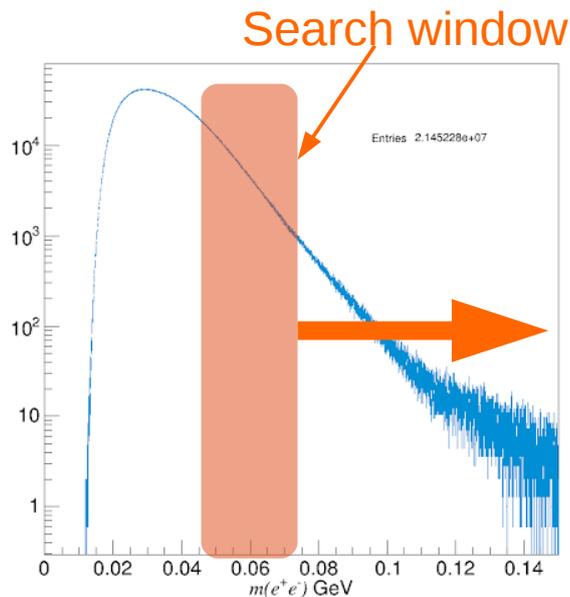

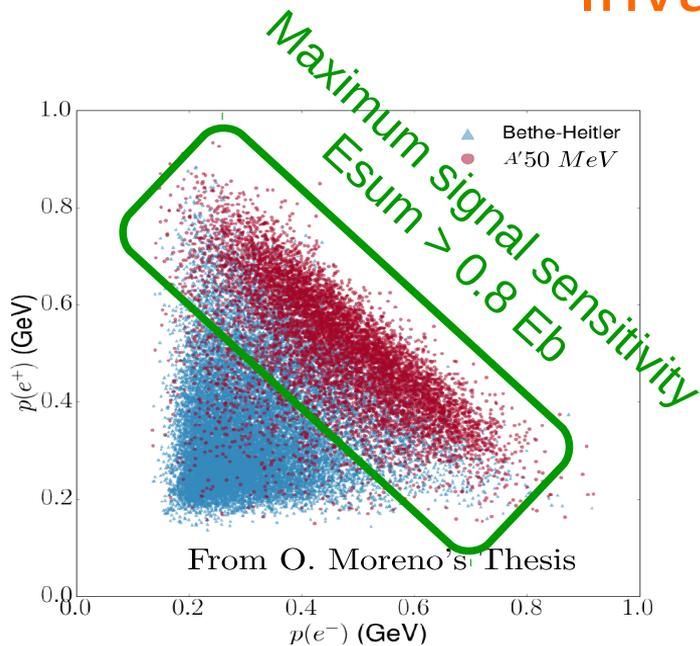

- Linear fit of MC A' masses
- Scale MC to match the data Moller resolution

# Invariant mass distribution

- Range 19 MeV – 81 MeV
- Scan w/ 0.5 MeV step
- Search for the peak in the given mass range
- Maximize Poisson Likelihood with Bgr only, and Bgr+signal hypothesis
- Use log likelihood ratio to quantify any excess/bump

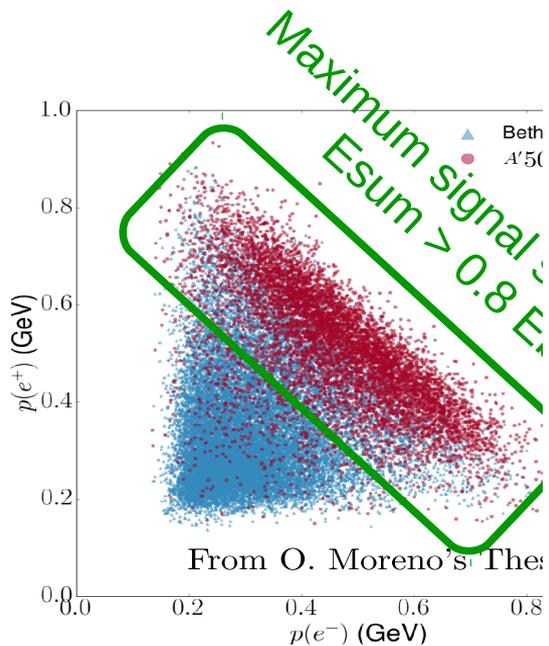

# Invariant mass distribution

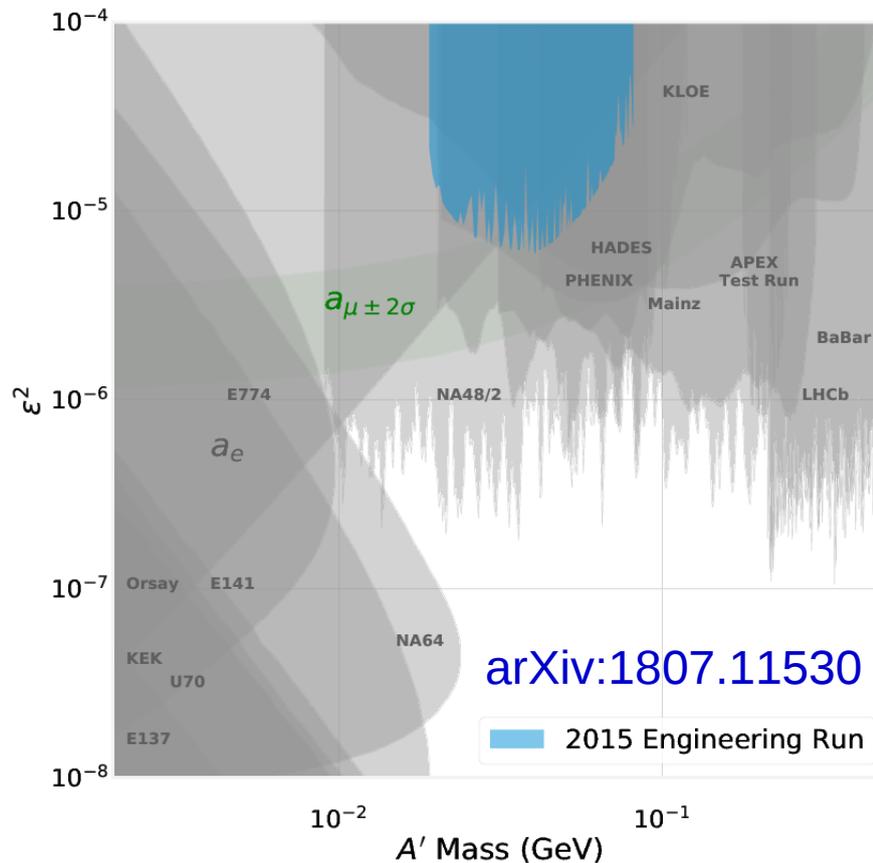

- Range 19 MeV – 81 MeV
- Scan w/ 0.5 MeV step
- Search for the peak in the given mass range
- Maximize Poisson Likelihood with Bgr only, and Bgr+signal hypothesis
- Use log likelihood to quantify any bump

**NO significant bump is found!  
2 $\sigma$  upper limit is placed**

# Invariant mass distribution

NO  $\epsilon$   
 $2\sigma$  u

range 19 MeV – 81 MeV

scan w/ 0.5 MeV step

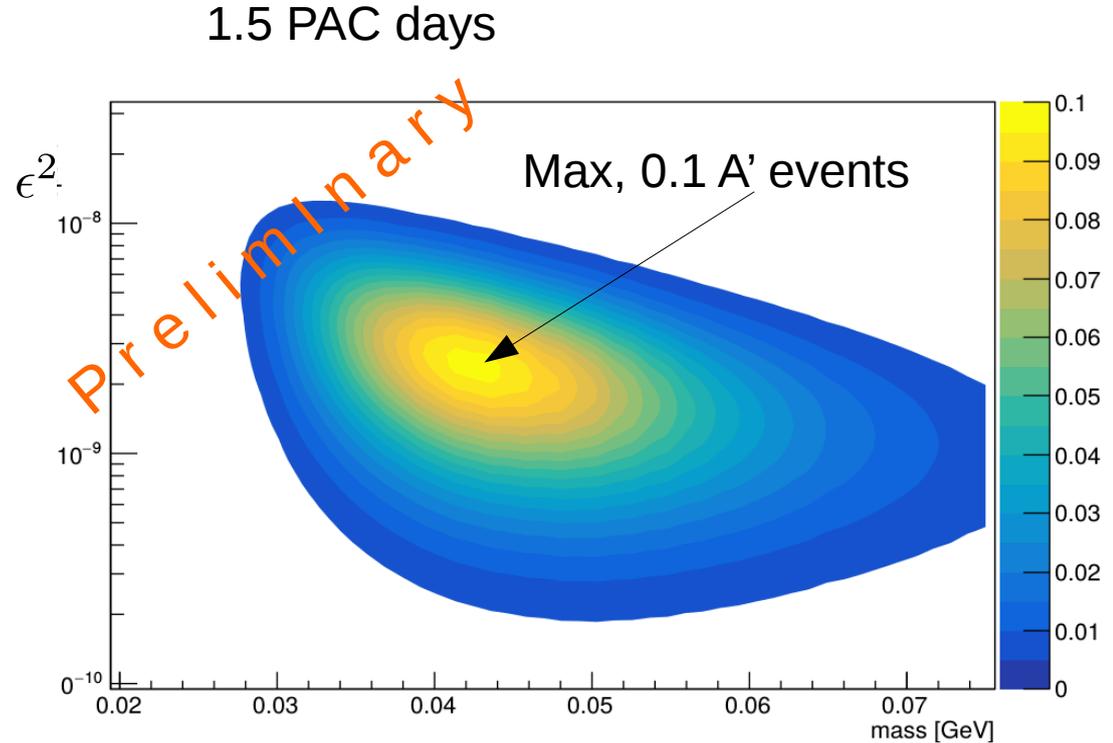

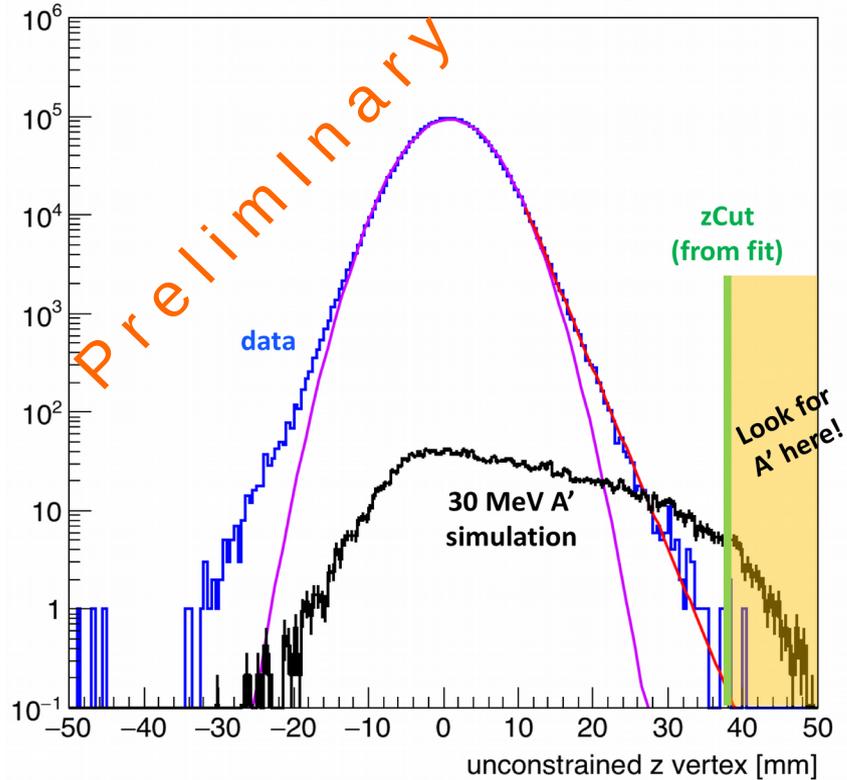

search for the peak in the given range

optimize Poisson Likelihood with background only, and Bgr+signal hypothesis

use log likelihood to quantify any exclusion

Submitted to PhysRevD RC

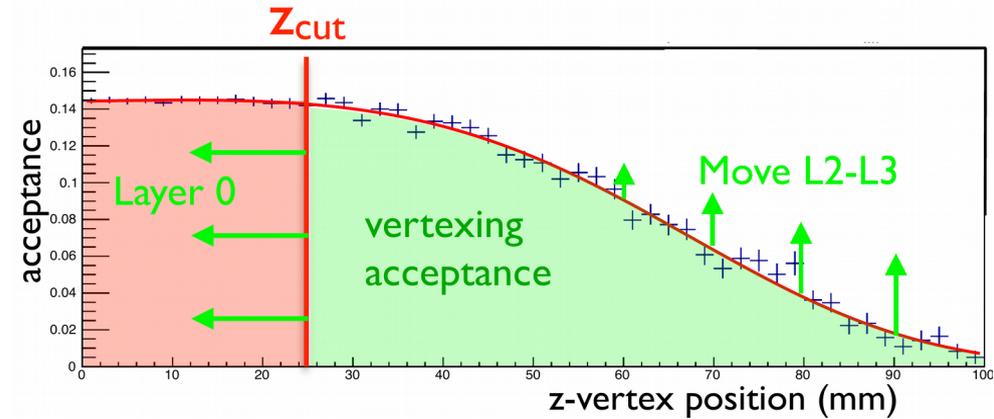

# Vertexing analysis

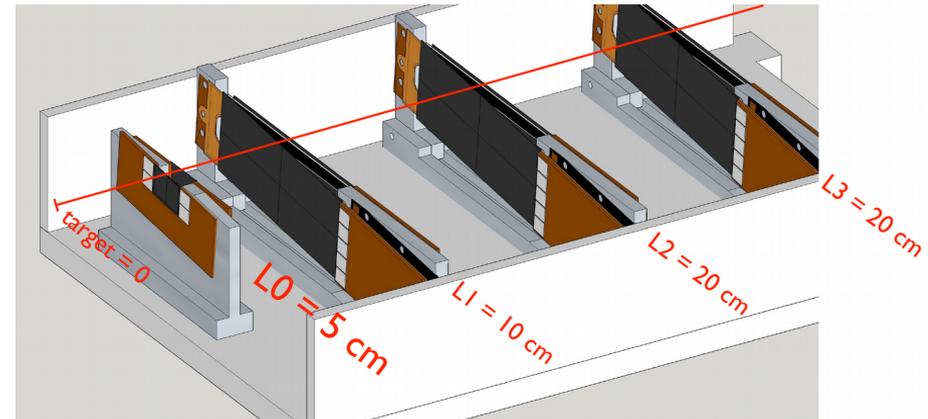

Analysis is in a quite advanced state, however with 1.5 days of data, we will not have any reach (2.5 expected A' events)

# SVT Upgrade

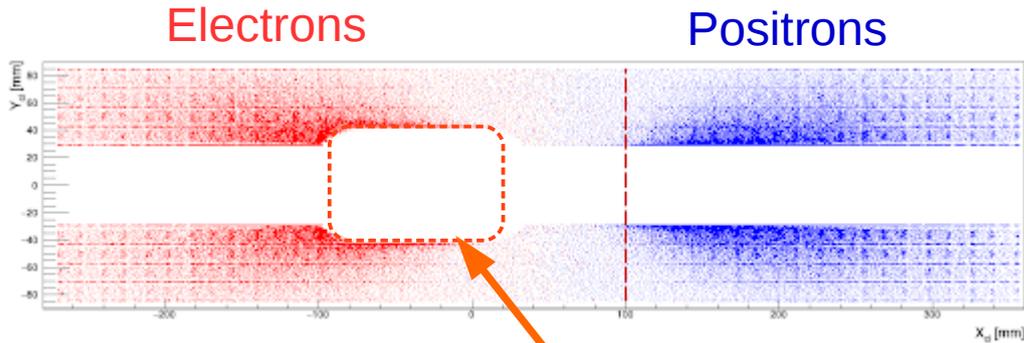

-Adding a new thin SVT layer at 5 cm downstream of the target, will significantly improve the vertexing resolution

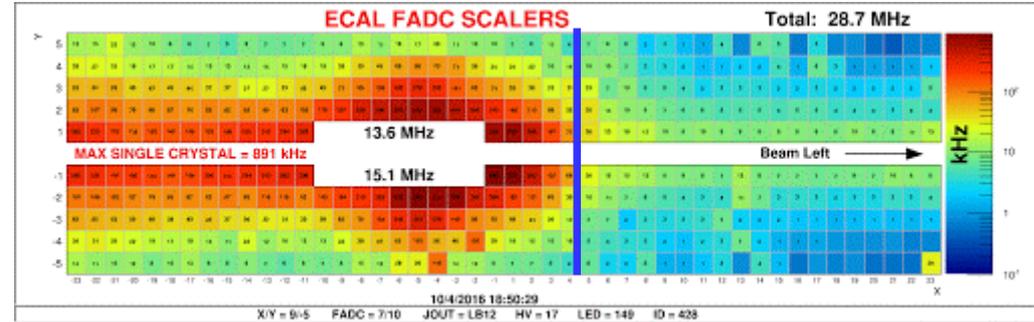

-Moving SVT Layers 2-3 closer to the beam will increase the acceptance

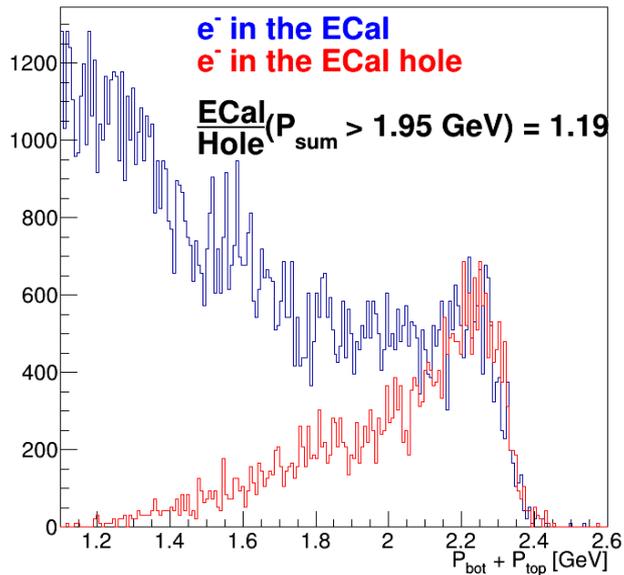

# HPS upgrades

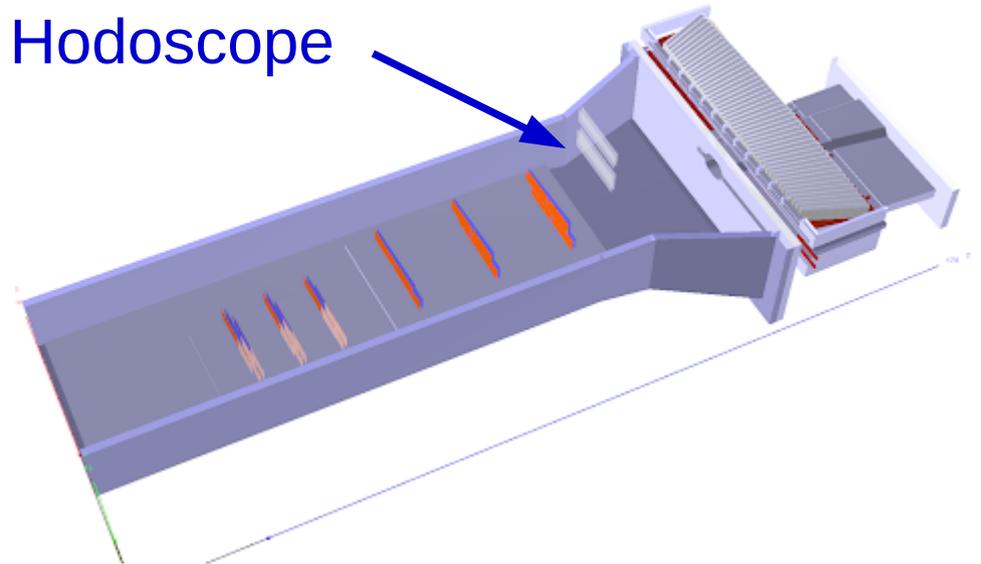

Low rate in positron side

Events w/ electron in the gap are lost

Hodoscope

# HPS future

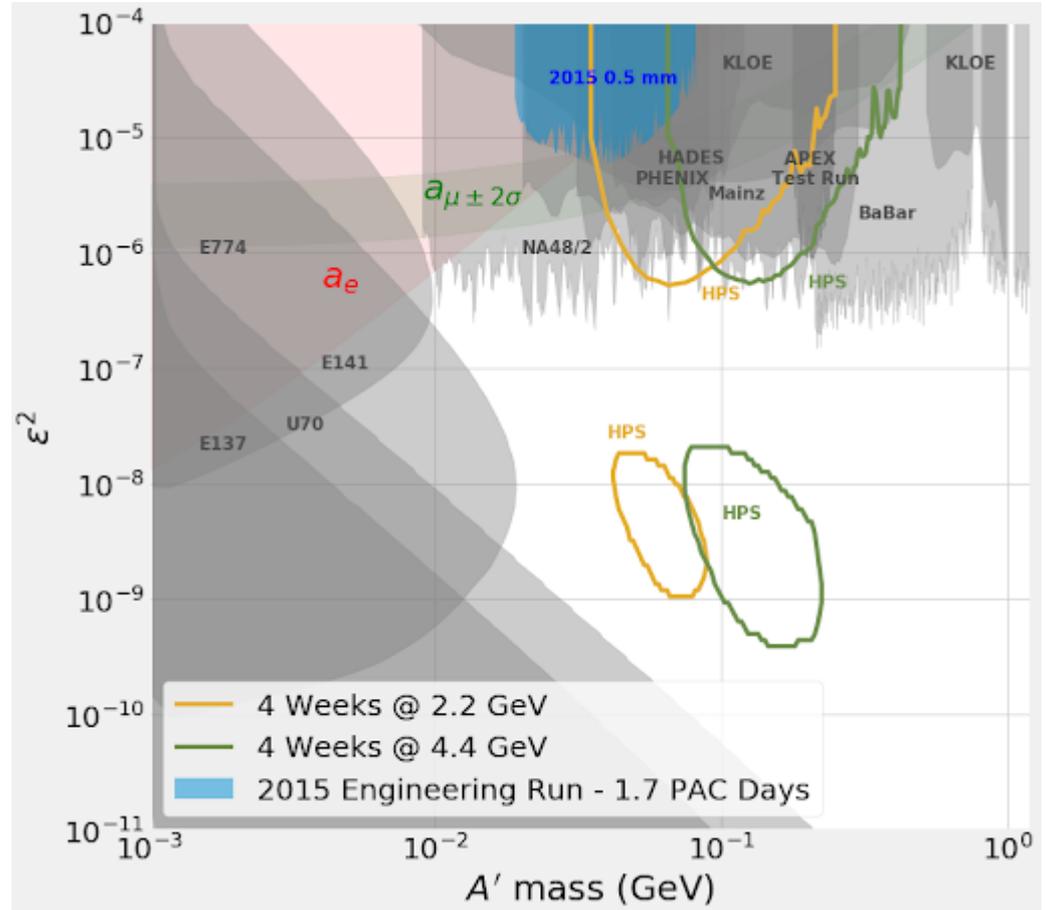

HPS is preparing to run starting Jun 2019 for 8 calendar weeks

Will be upgraded with two detector components, L0 and Hodoscope

Hodo upgrade is expected to increase the reach by about x2

SVT upgrades will significantly improve the vertexing resolution and acceptance and hence the HPS vertexing reach

It is expected to have a vertex reach, and covered territory!

# Summary

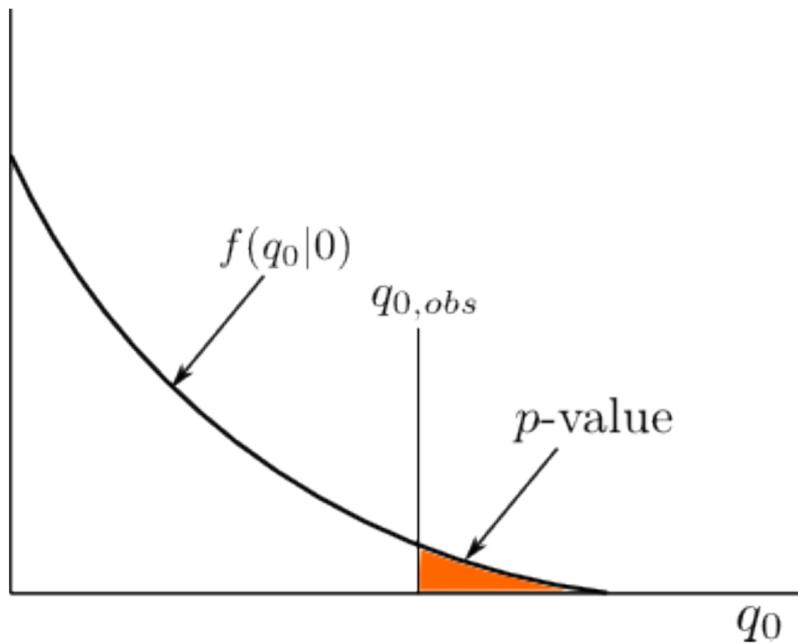

JLab has a broad program in dark sector physics

JLab experiments have capability to cover new uncovered territories

It is exciting time for Dark matter experiments, two of them (APEX and HPS) will take significant amount of data in 2019

1 published paper (APEX test run), 1 submitted (HPS 2015), and more should come (HPS 2016 data, and upcoming experiments)

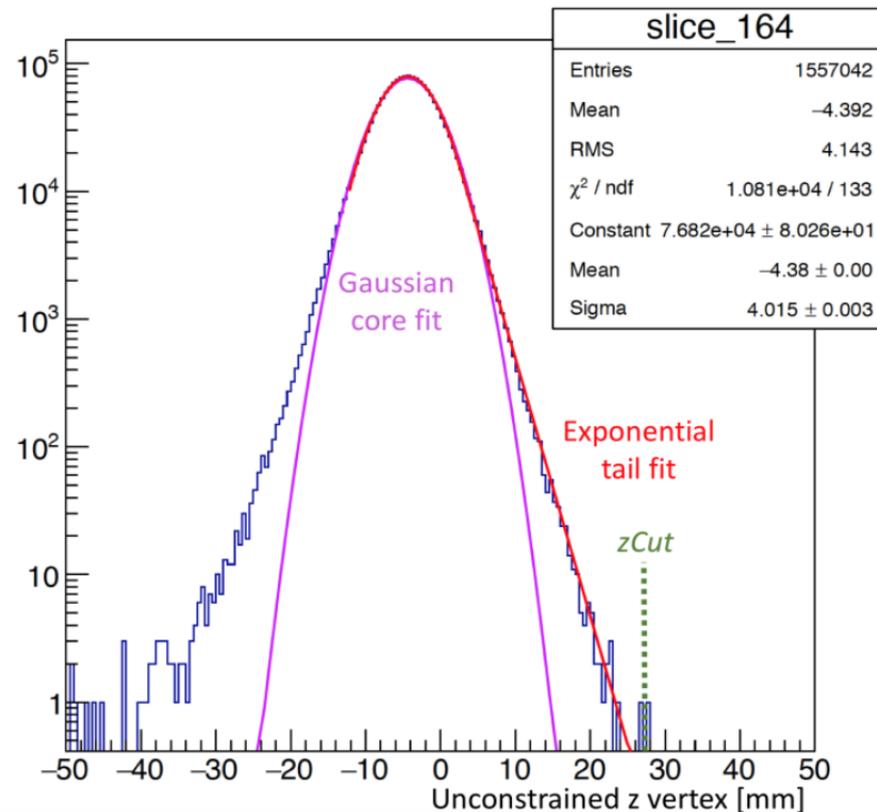

# Supporting slides

$$q_0 = \begin{cases} -2 \ln \frac{\mathcal{L}(0, \hat{\theta})}{\mathcal{L}(\hat{\mu}, \hat{\theta})} & \hat{\mu} > 0 \\ 0 & \hat{\mu} < 0. \end{cases}$$

$$F(z < b) = Ae^{-\frac{(z - z_{mean})^2}{2\sigma^2}}$$

$$F(z > b) = Ae^{-\frac{b^2}{2\sigma^2} - \frac{z - z_{mean} - b}{l}}$$

### Vertex Resolution
