QNP2022 - The 9th International Conference on Quarks and Nuclear Physics

Origin of proton asymmetry	Exploring the Sea	Models 0000	<u>Х СОМ</u> 000000	Results 0000	Conclusion 00
Outline					

- The proton picture with just three valence quarks (*uud*) fail to explain the fractional momentum carried by the constituents.
  - If there were only three valence quarks, each quark should have carried  $\frac{1}{3}$  of proton's total momentum.
  - This was found to be untrue.
  - Average fractional momentum carried by the constituents was less than  $\frac{1}{3}$ .
- The extra momentum was attributed to *sea quarks*.

### Gottfried Sum Rule (GSR)

Exploring the Sea

• GSR suggests that if the sea is symmetric, then the value of Gottfried integral  $(I_G) = \frac{1}{3} + \frac{2}{3} \int_0^1 [\bar{u}(x) - \bar{d}(x)] dx = \frac{1}{3}$ .

XCOM

#### Gottfried Integral $(I_G)$

Origin of proton asymmetry

$$I_G=rac{1}{3}\Rightarrow$$
 symmetric sea  $ar{u}=ar{d}$  .

$$U_G < rac{1}{3} \Rightarrow$$
 asymmetric sea  $ar{u} 
eq ar{d}$  .

#### • Violation of GSR is a direct evidence of *asymmetric sea*.

#### Feynman's interpretation

- SLAC data reported  $I_G = 0.20 \pm 0.04$ .
- Feynman's intuitive interpretation for proton's asymmetric sea was as follows :
  - $u\bar{u}$  and  $d\bar{d}$  pairs are produced perturbatively due to gluon splitting.
  - $u\bar{u}$  production is suppressed because proton already contains two valence *up* quarks (*Pauli blocking*).
  - This naturally leads to an excess of  $d\bar{d}$  pairs and hence  $\bar{d}$  outnumbers  $\bar{u}$  inside the proton.
- Observed asymmetry too large to be explained by this alone.

Models 0000 <u>х сом</u> 000000

#### Deep Inelastic Scattering (DIS) experiments

- Usually addresses the difference  $\bar{d} \bar{u}$ .
- Great for measuring
   Gottfried Integral (*I<sub>G</sub>*).
- Can not extract individual anti-quark distribution.

# • Various *DIS* experiments were conducted and all of them reported $I_G < \frac{1}{3}$ .

Experiment	<b>Gottfried Integral</b> $(I_G)$
SLAC	$0.200\pm0.040$
EMC	$0.235\pm0.099$
NMC	$0.235\pm0.026$
HERMES	$0.226\pm0.020$

0000

## Drell-Yan (DY) experiments

• Ratio of DY cross-section :

$$rac{\sigma^{pd}}{2\sigma^{pp}} pprox rac{1}{2} \left( 1 + rac{ar{d}(x)}{ar{u}(x)} 
ight)$$

- An effective way to measure  $\frac{\bar{d}}{\bar{u}}$  ratio.
- Can extract individual anti-quark distribution.

Exploring the	Sea				

- Later experiments were based on Drell-Yan (DY) process.
- NA51 was first dedicated DY experiment and found  $\frac{\ddot{u}}{d} = 0.51 \pm 0.04$  at x = 0.18
- NuSea reported both  $\frac{\bar{d}}{\bar{u}}$  and  $\bar{d} \bar{u}$  data.

Experiment	<b>Gottfried Integral</b> $(I_G)$
E866/NuSea	$0.254\pm0.005$

lodels

#### NuSea and SeaQuest Results

- Around  $x \approx 0.3$  NuSea reported  $rac{ar{d}}{ar{u}} < 1$
- SeaQuest specifically collected data in medium to high *x* range.
- *Disagreement* between NuSea and SeaQuest data in high x region.

Origin of proton asymmetry	Exploring the Sea	Models ●000	<u>Х сом</u> 000000	Results 0000	Conclusion 00

#### Theoretical attempts

- Significant  $\bar{u} \ \bar{d}$  asymmetry in protons can not be explained perturbatively.
- Some *non-perturbative* models are :
  - Pion Cloud Model.
  - Chiral Constituent Quark Model ( $\chi_{CQM}$ )
  - Instanton Model
- Pion Cloud Model and  $\chi_{CQM}$  both involve mesons in their explanations.

• In PCM, proton can momentarily exist as a *virtual pion* and a baryon.

•  $|p
angle = (1-a-b) |p_0
angle + a |n\pi^+
angle + b |\Delta^{++}\pi^angle$ 

- It is more probable for proton to exist as  $|n\pi^+
  angle$  than  $|\Delta^{++}\pi^angle$ 
  - $uud \rightarrow (udd)(\bar{d}u) \rightarrow uud$
  - $\mathit{uud} 
    ightarrow (\mathit{uuu})(\bar{\mathit{u}}\mathit{d}) 
    ightarrow \mathit{uud}$
- a > b causes excess of  $\overline{d}$ .
- There are other baryons but generally neutron and delta considered.

Origin of proton asymmetry	Exploring the Sea	Models 0000	<u>Х сом</u> 000000	Results 0000	Conclusion 00
ХСОМ					

- In χ<sub>CQM</sub>, valence quark q can transition into a Goldstone Boson (GB) and a valence quark q' (different flavor).
   q<sup>±</sup> → GB + q'<sup>±</sup>
- Valence *up* and *down* quarks can transition with maximum probability into a  $\pi^+$  and  $\pi^-$  GB.

• 
$$u \to \pi^+ d \to (u\bar{d})(d)$$

- $d \rightarrow \pi^- u \rightarrow (d \bar{u})(u)$
- Two valence up quarks in proton causes excess of  $\bar{d}$ .
- Other GBs are K,  $\eta$  and  $\eta'$ .

Origin of proton asymmetry

- Successfully explains the "proton spin problem".
- Can account for baryon magnetic moments.
- Calculates charge radii and quadrupole moment of baryons.

Models

XCQM

- Incorporates *chiral symmetry breaking* and *confinement*, two key features of *QCD*.
- Mechanism involving GBs operate in the *interior* of proton.

• QCD Lagrangian describes the dynamics of light quarks (*up*, *down* and *strange*) and gluons.

• 
$$\mathcal{L}_{QCD} = -\frac{1}{4} G^a_{\mu\nu} G^{\mu\nu}_a + i \bar{\psi}_R D \psi_R + i \bar{\psi}_L D \psi_L - \bar{\psi}_L M \psi_R - \bar{\psi}_R M \psi_L$$

- It is not invariant under chiral transformation ( $\psi \rightarrow \gamma^5 \psi$ ) due to presence of mass terms.
- At high energies mass terms can be neglected and Lagrangian has a  $SU(3)_L \times SU(3)_R$  global chiral symmetry.

• At low energies mass terms can no longer be neglected and chiral symmetry is *spontaneously broken* as :

•  $SU(3)_L \times SU(3)_R \rightarrow SU(3)_{L+R}$ 

• This happens at pprox 1 GeV.

Origin of proton asymmetry

- As a result an *octet* of GBs is generated, comprising of  $\pi$ , K and  $\eta$  mesons.
- $\mathcal{L}_{QCD}$  also invariant under axial U(1) symmetry, when this is broken, a ninth GB  $\eta'$  is also generated.

#### Quark-GB Interaction

Origin of proton asymmetry

• Interaction between the quarks and *nonet* of GBs is the basis of  $\chi_{CQM}$ . It is described by  $\mathcal{L}_{int} = g_8 \bar{\psi} \varphi' \psi$ .

*χ com* 

•  $g_8 :=$  Coupling constant for octet of GBs.

Exploring the Sea

•  $\varphi' \coloneqq \mathsf{GB}$  field in terms of nonet and their transition probabilities.

$$\varphi' = \begin{pmatrix} \frac{\pi^{0}}{\sqrt{2}} + \kappa \frac{\eta}{\sqrt{6}} + \frac{\xi \eta'}{\sqrt{3}} & \pi^{+} & \lambda K^{+} \\ \pi^{-} & -\frac{\pi^{0}}{\sqrt{2}} + \frac{\kappa \eta}{\sqrt{6}} + \frac{\xi \eta'}{\sqrt{3}} & \lambda K^{0} \\ \lambda K^{-} & \lambda \overline{K^{0}} & -\frac{\kappa 2 \eta}{\sqrt{6}} + \frac{\xi \eta'}{\sqrt{3}} \end{pmatrix}$$

igin of proton asymmetry	Exploring the Sea	Models 0000	<i>χ com</i> 000€00	Results 0000	Conclusion 00
--------------------------	-------------------	----------------	------------------------	-----------------	------------------

*Transition probability* is inversely proportional to the mass of GB

and scales as  $\frac{1}{Mc_{B}^{2}}$ . This sets the constraint  $\varepsilon > \varepsilon \lambda^{2} > \varepsilon \kappa^{2} > \varepsilon \xi^{2}$ .

#### **Probability Parameters**

- Transition
  - $u(d) \rightarrow \pi^{+(-)} + d(u)$
  - $u(d) \rightarrow K^{+(0)} + s$

Hierarchy of Probabilities

- $u(d,s) \rightarrow \eta + u(d,s)$
- $u(d,s) \rightarrow \eta' + u(d,s)$

• Probability

● E

•  $\varepsilon \lambda^2$ 

•  $\varepsilon \kappa^2$ 

•  $\varepsilon \xi^2$ 

0000

*χ com* 

Conclusion 00

#### Calculating Asymmetry

$$\bar{u} = \varepsilon \left( \frac{7}{4} + \frac{\kappa^2}{12} + \frac{\xi}{3} + \frac{\xi^2}{3} + \frac{\kappa}{6} + \frac{\kappa\xi}{6} \right)$$
$$\bar{d} = \varepsilon \left( \frac{11}{4} + \frac{\kappa^2}{12} - \frac{\xi}{3} + \frac{\xi^2}{3} - \frac{\kappa}{6} - \frac{\kappa\xi}{3} \right)$$

#### ūd asymmetry

Taking  $\varepsilon = 0.114$ ,  $\kappa = 0.45$  and  $\xi = -0.75$  we obtain  $\bar{u} - \bar{d} = -0.118$  and  $\bar{u}/\bar{d} = 0.652$ 

#### Incorporating x dependence in $\chi_{CQM}$

Exploring the Sea

Origin of proton asymmetry

- Parton distributions can not be calculated from the first principles yet and are determined experimentally.
- To make anti-quark distribution  $\bar{u}$  and  $\bar{d}$  x-dependent, we have multiplied it with a function of form  $(Nx)^a(1-x)^b(1+Cx)$ .
- Parameters N, a, b and C are chosen such that d(x)/d(x) and d(x) u(x) are consistent with experimental data from NuSea, SeaQuest and HERMES.

Models 0000

<u>х сом</u> 000000 Results ●000 Conclusion

#### Explicit sea quark distribution functions.

$$ar{d}(x) = 0.3391(1.5x)^{-1}(1-x)^{10}(1+12.0569x)$$

Probability density: *up* sea quark

$$\bar{u}(x) = 0.2211x^{-0.999}(1-x)^{7.4}(1+2.0876x)$$

Gottfried Integral 
$$(I_G)$$
  $0.015 \le x \le 0.45$   
 $I_G = \frac{1}{3} + \frac{2}{3} \int_{x_{min}}^{x_{max}} [\bar{u}(x) - \bar{d}(x)] dx = 0.256$   
 $I_G = \frac{1}{3} + \frac{2}{3} \int_0^1 [\bar{u}(x) - \bar{d}(x)] dx = 0.210$

#### Parton momentum distribution

- Clear dominance of valence quark distribution for x > 0.3
- Sea quark distribution completely overshadows valence distribution at low x.

• *Excess of* 
$$\overline{d}$$
 over  $\overline{u}$  when  $x < 0.3$ 

 $\bar{d}(x)/\bar{u}(x)$  compared to SeaQuest and NuSea data

Origin of proton asymmetry

Exploring the Sea

•  $\frac{\overline{d}(x)}{\overline{u}(x)} \ge 1$  in the region  $x \le 0.35$ •  $\frac{\overline{d}(x)}{\overline{u}(x)} \ge 1$  for x > 0.35. This is valence quark dominated region. • Ratio peaks at x = 0.133 then gradually decays.

Results

• No model has yet explained why the ratio drops below unity at high *x*.

Origin of proton asymmetry

odels OO <u>х сом</u> 000000 Conclusion

## $ar{d}(x) - ar{u}(x)$ compared to HERMES and NuSea data

\$\bar{d}(x) - \bar{u}(x)\$ is consistent with other models in that it does not change sign in 0.30 < x < 0.35</li>

• The difference between *PCM* and  $\chi_{CQM}$  in the low x region is due to their distinct mechanisms.

Origin of proton asymmetry	Exploring the Sea	Models 0000	<u>Х сом</u> 000000	Results 0000	Conclusion ●○
Conclusion					

- In  $\chi_{CQM}$ , GBs generated due to spontaneous chiral symmetry breaking are the basis of sea quark asymmetry in proton.
- Sea quarks carry most of proton's momentum at low x and  $\bar{d}$  outnumbers  $\bar{u}$  in this region.
- For x > 0.3 proton's momentum is mostly carried by valence quarks.
