

Color Propagation Studies in CLAS: Present and Future

Will Brooks, for the EG2⁺⁺ CP Group

EG2++ Physics

- Color Propagation (today's topic)
- Color Transparency
- Short-range Nucleon-Nucleon Correlations
- Di-hadron Correlations (some on this today too)
- Much more!

Physics Thrusts of Color Propagation Studies

- Fundamental properties of QCD Color Propagation in hadronization
 - Characterize the two stages of color propagation: quasi-free quark and forming hadron (**asymptotic freedom → confinement**)
 - Use nuclei as spatial filters to determine time scales via distances
- Quark structure of nuclei
 - the \hat{q} transport coefficient is the primary measure of parton interaction with medium
 - Δp_T^2 observable (${}_\infty \hat{q}$) measures quark-gluon correlation function $T^A_{qF}(x_B, Q^2)$:

Guo and Qiu, PRD 61 (9) (2000) <http://dx.doi.org/10.1103/PhysRevD.61.096003>

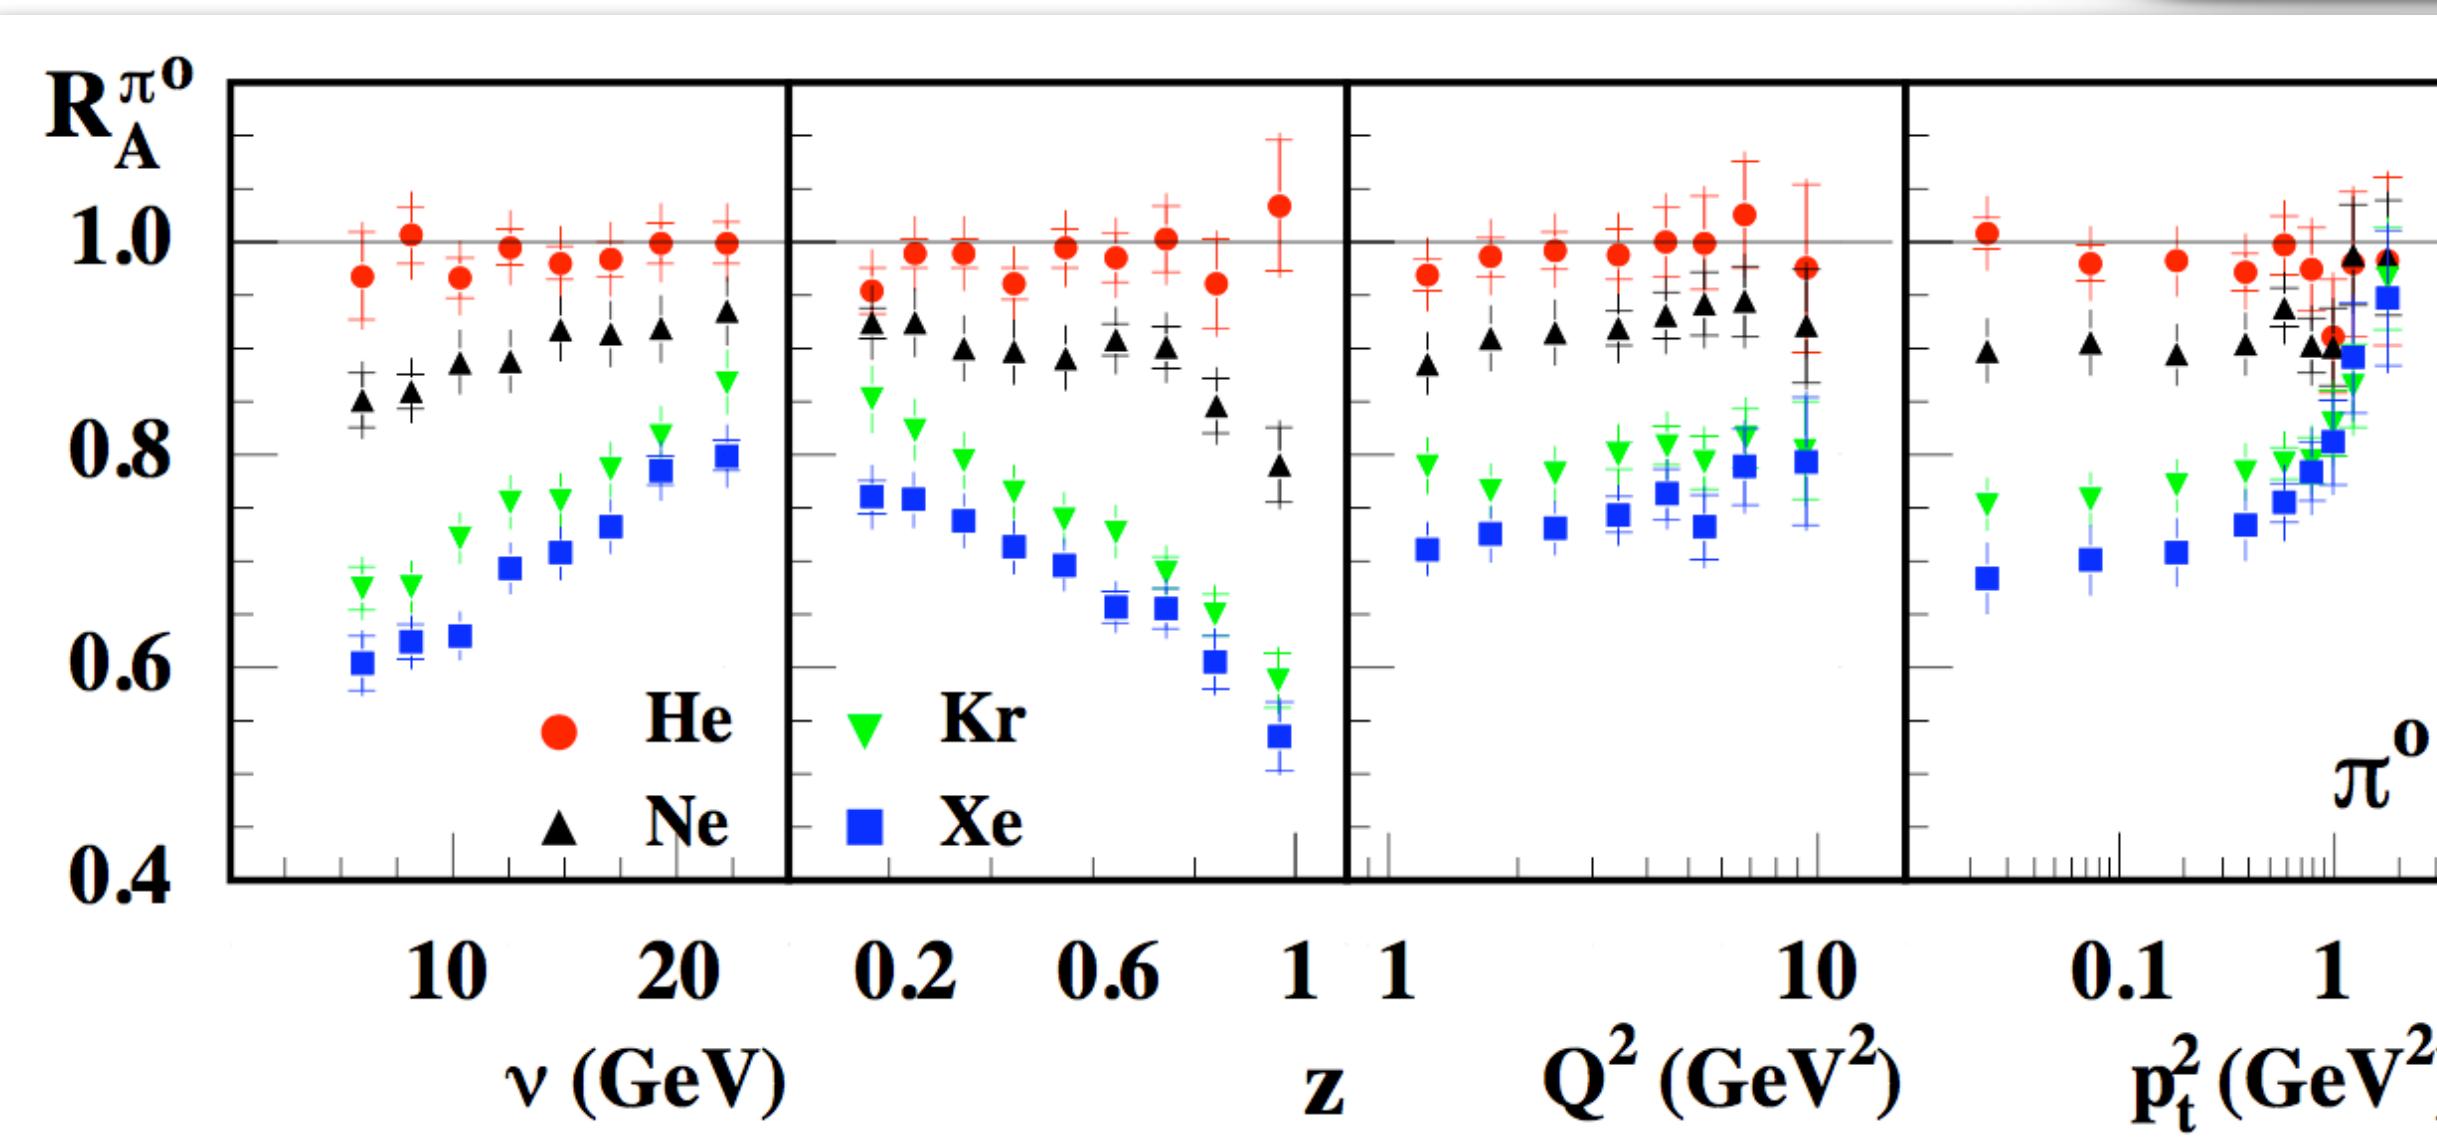

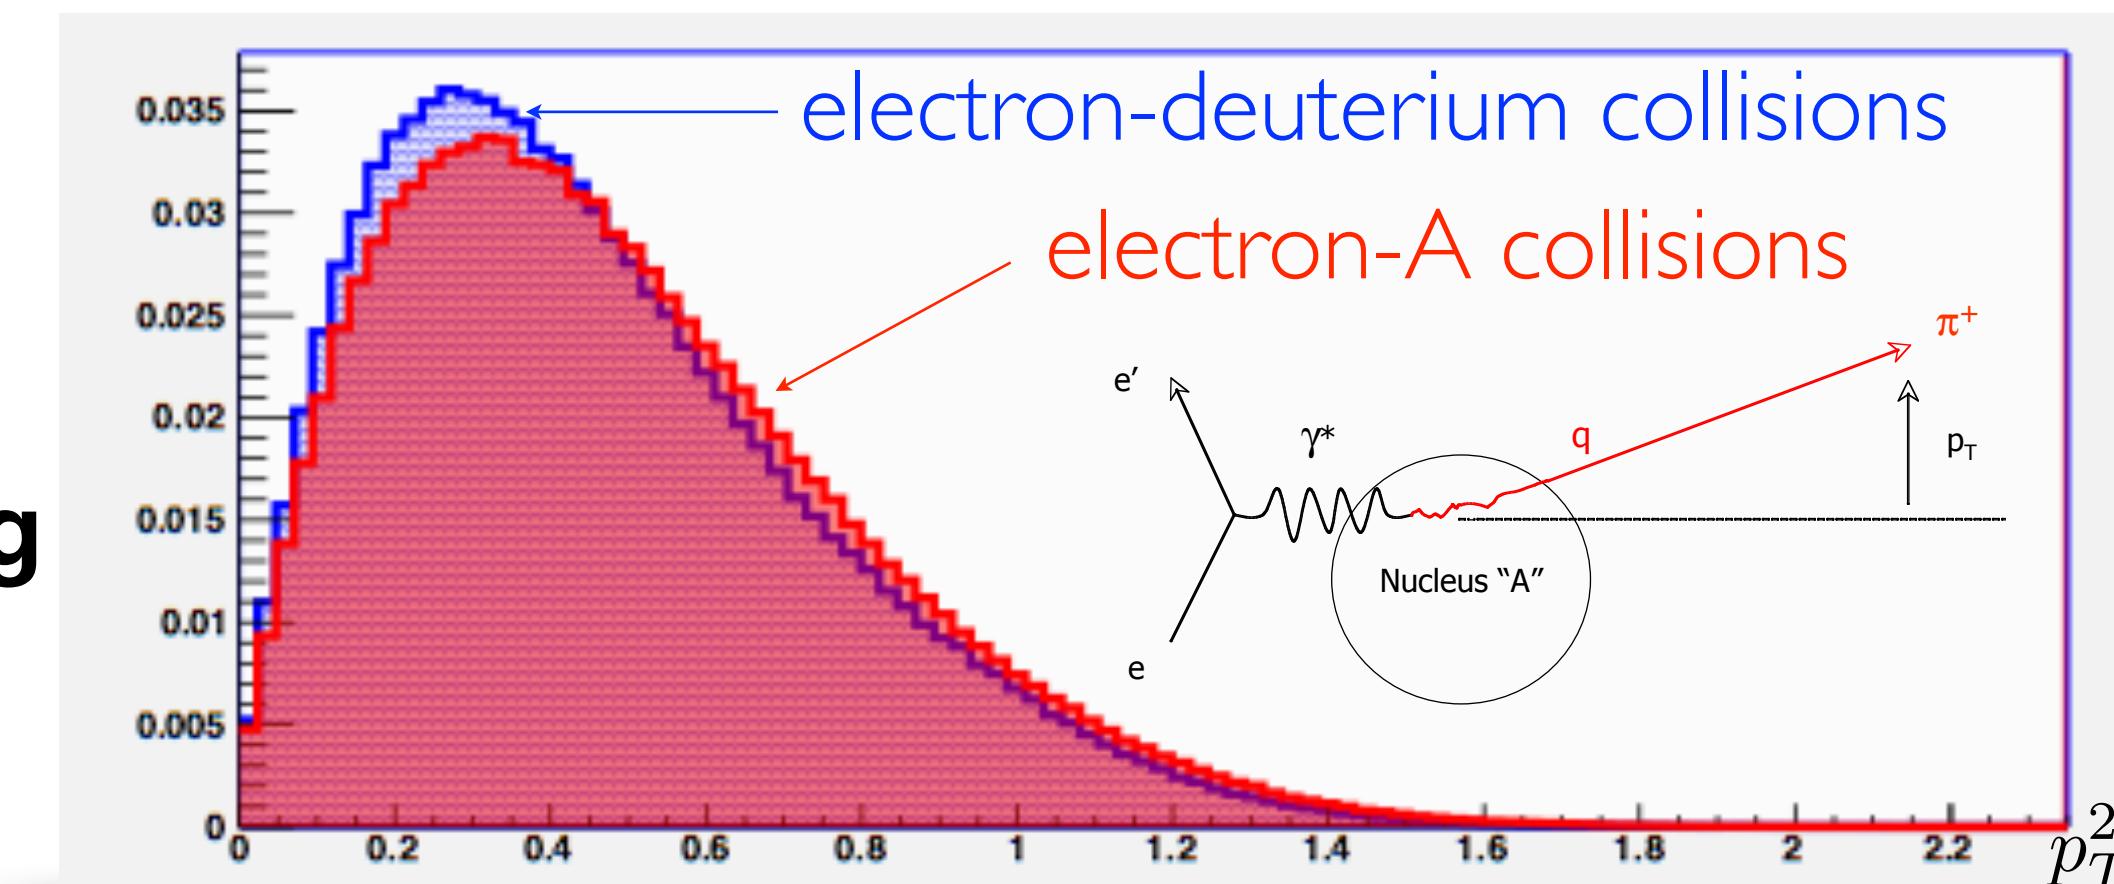

Luo, Qiu, Sterman, Phys. Rev. D 50 (1994) 1951– 1971. <https://link.aps.org/doi/10.1103/PhysRevD.50.1951>

XF Guo, Phys. Rev. D 58, 114033 (1998), <https://link.aps.org/doi/10.1103/PhysRevD.58.114033>

$$\Delta p_T^2(Q^2, \nu, z_h) \equiv \langle p_T^2(Q^2, \nu, z_h) \rangle |_A - \langle p_T^2(Q^2, \nu, z_h) \rangle |_D$$

Experimental Observables

Transverse momentum broadening
typical value <0.05 GeV²

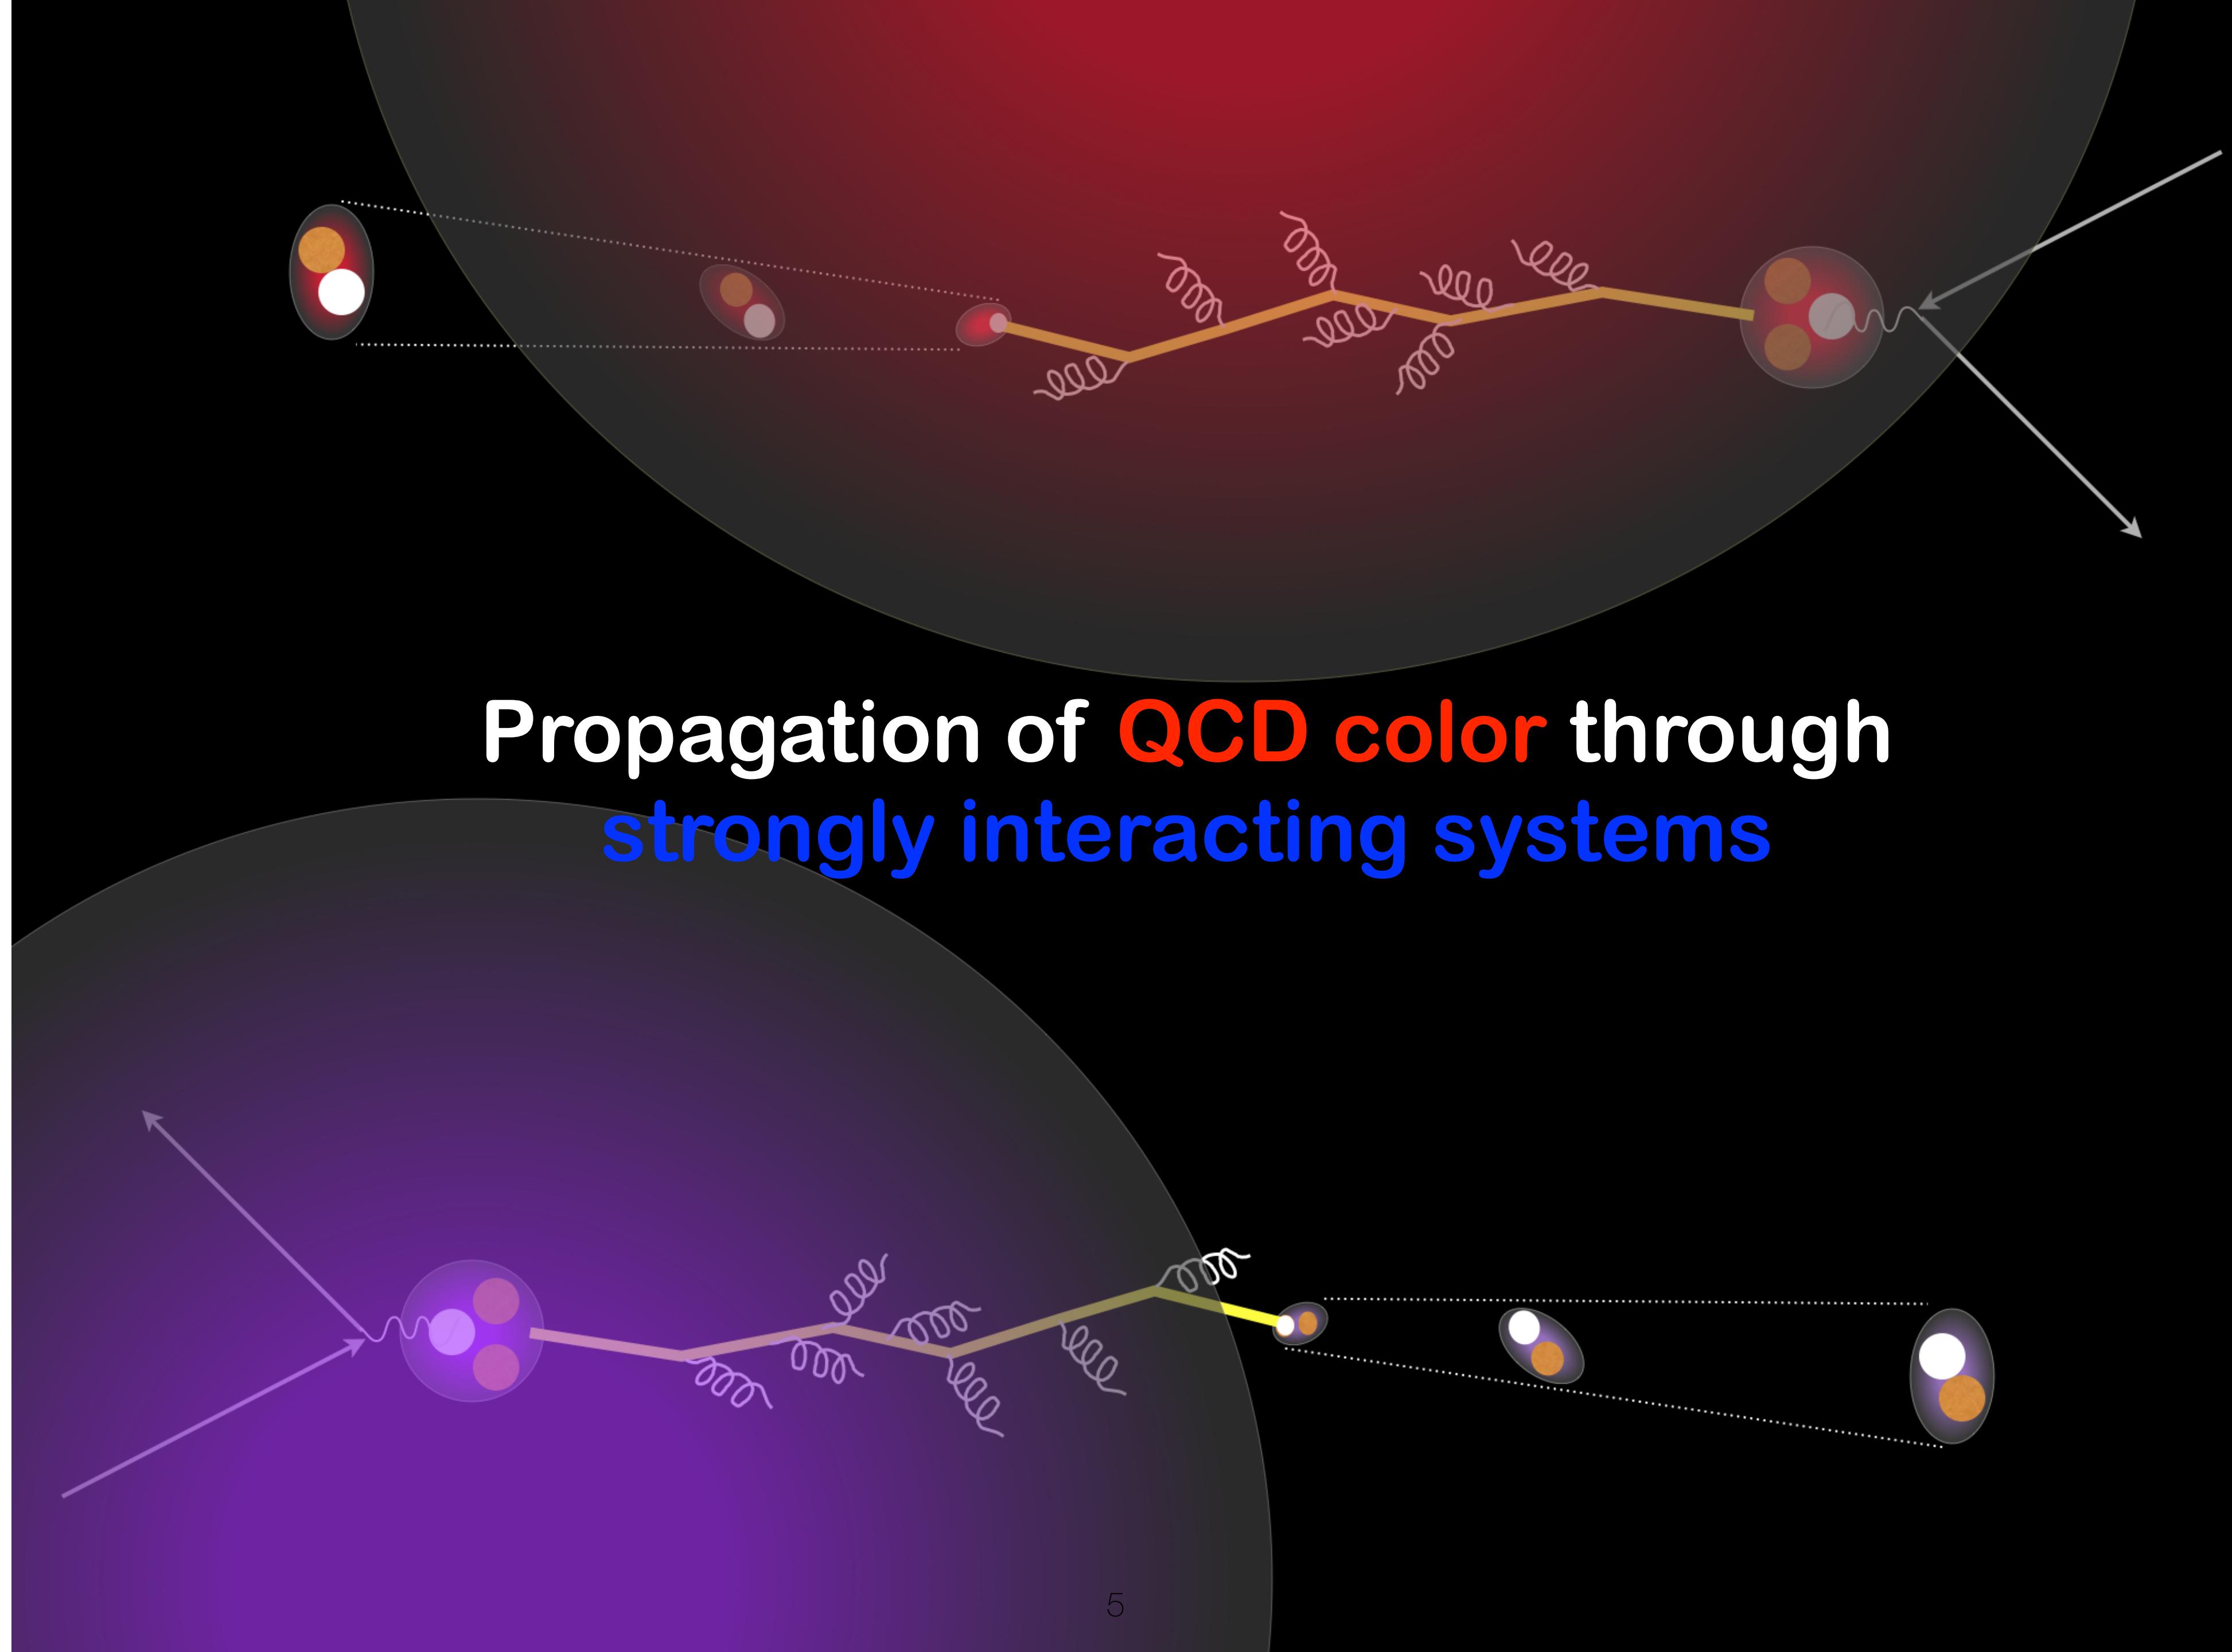

Hadronic multiplicity ratio (MR)
= 1 if no nuclear effects

← Neutral pion MR from HERMES. CLAS
results will be shown in slides 14-15!

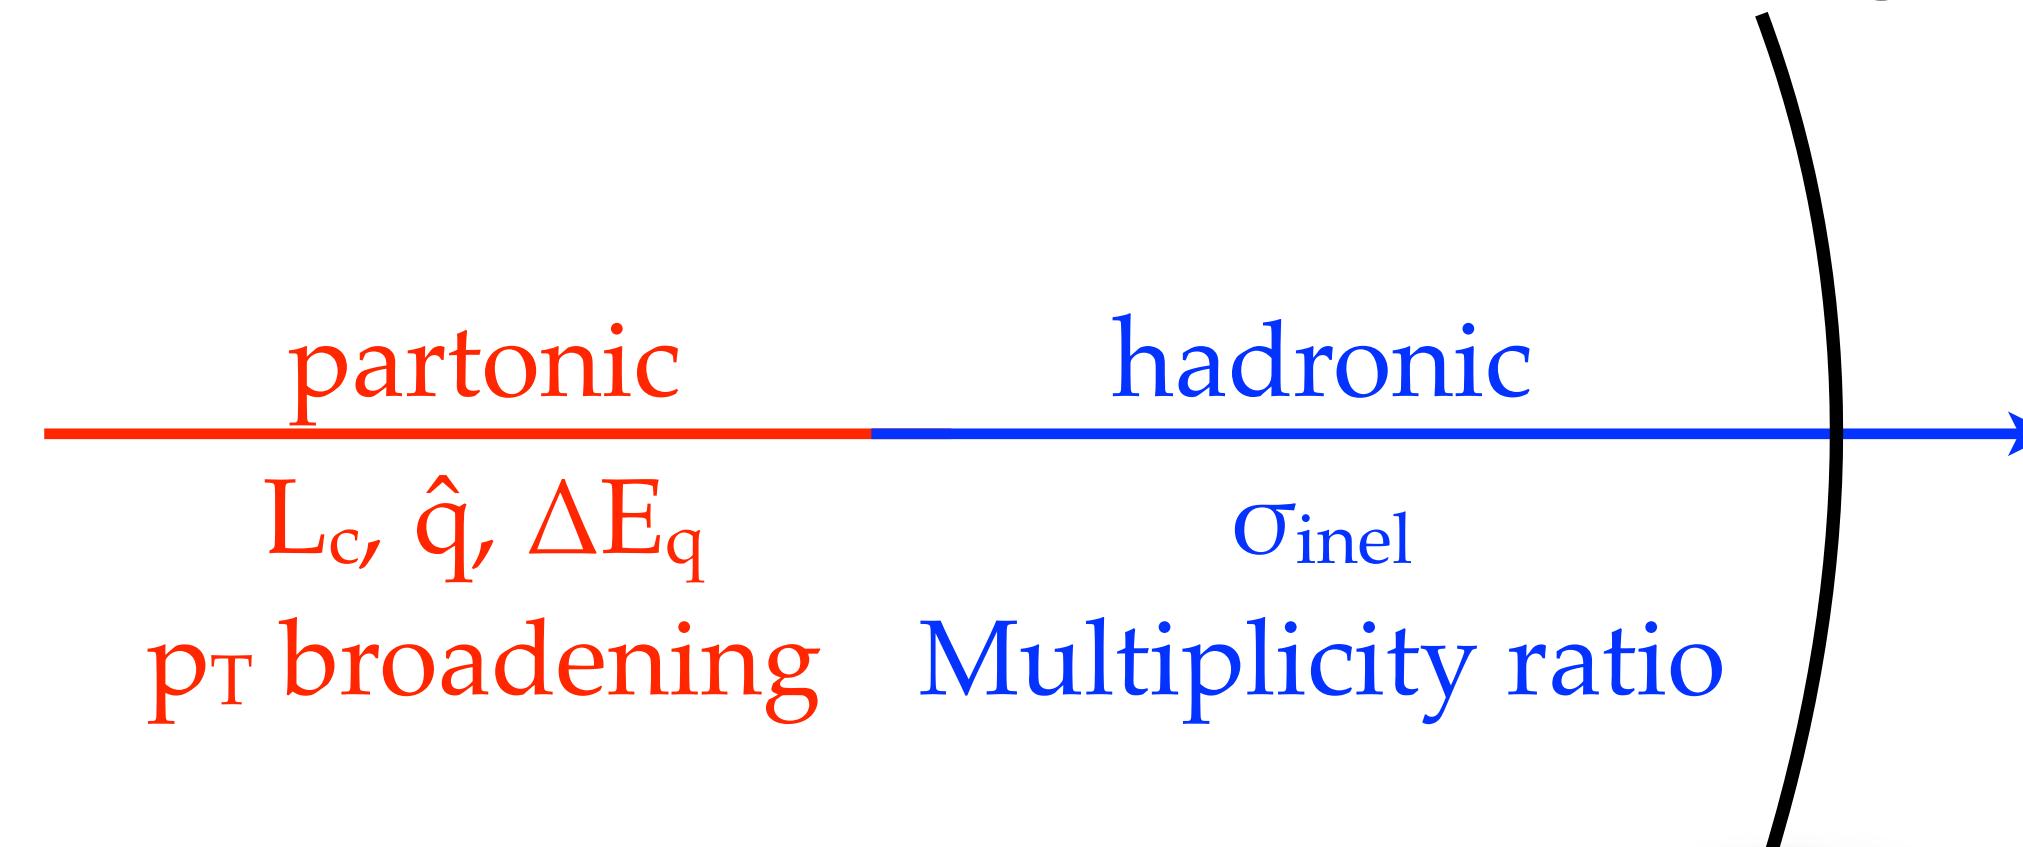

$$R_M^h(Q^2, \nu, z_h, p_T) \equiv \frac{\frac{1}{N_e(Q^2, \nu)} \cdot N_h(Q^2, \nu, z_h, p_T)|_A}{\frac{1}{N_e(Q^2, \nu)} \cdot N_h(Q^2, \nu, z_h, p_T)|_D}$$

Propagation of **QCD color** through strongly interacting systems

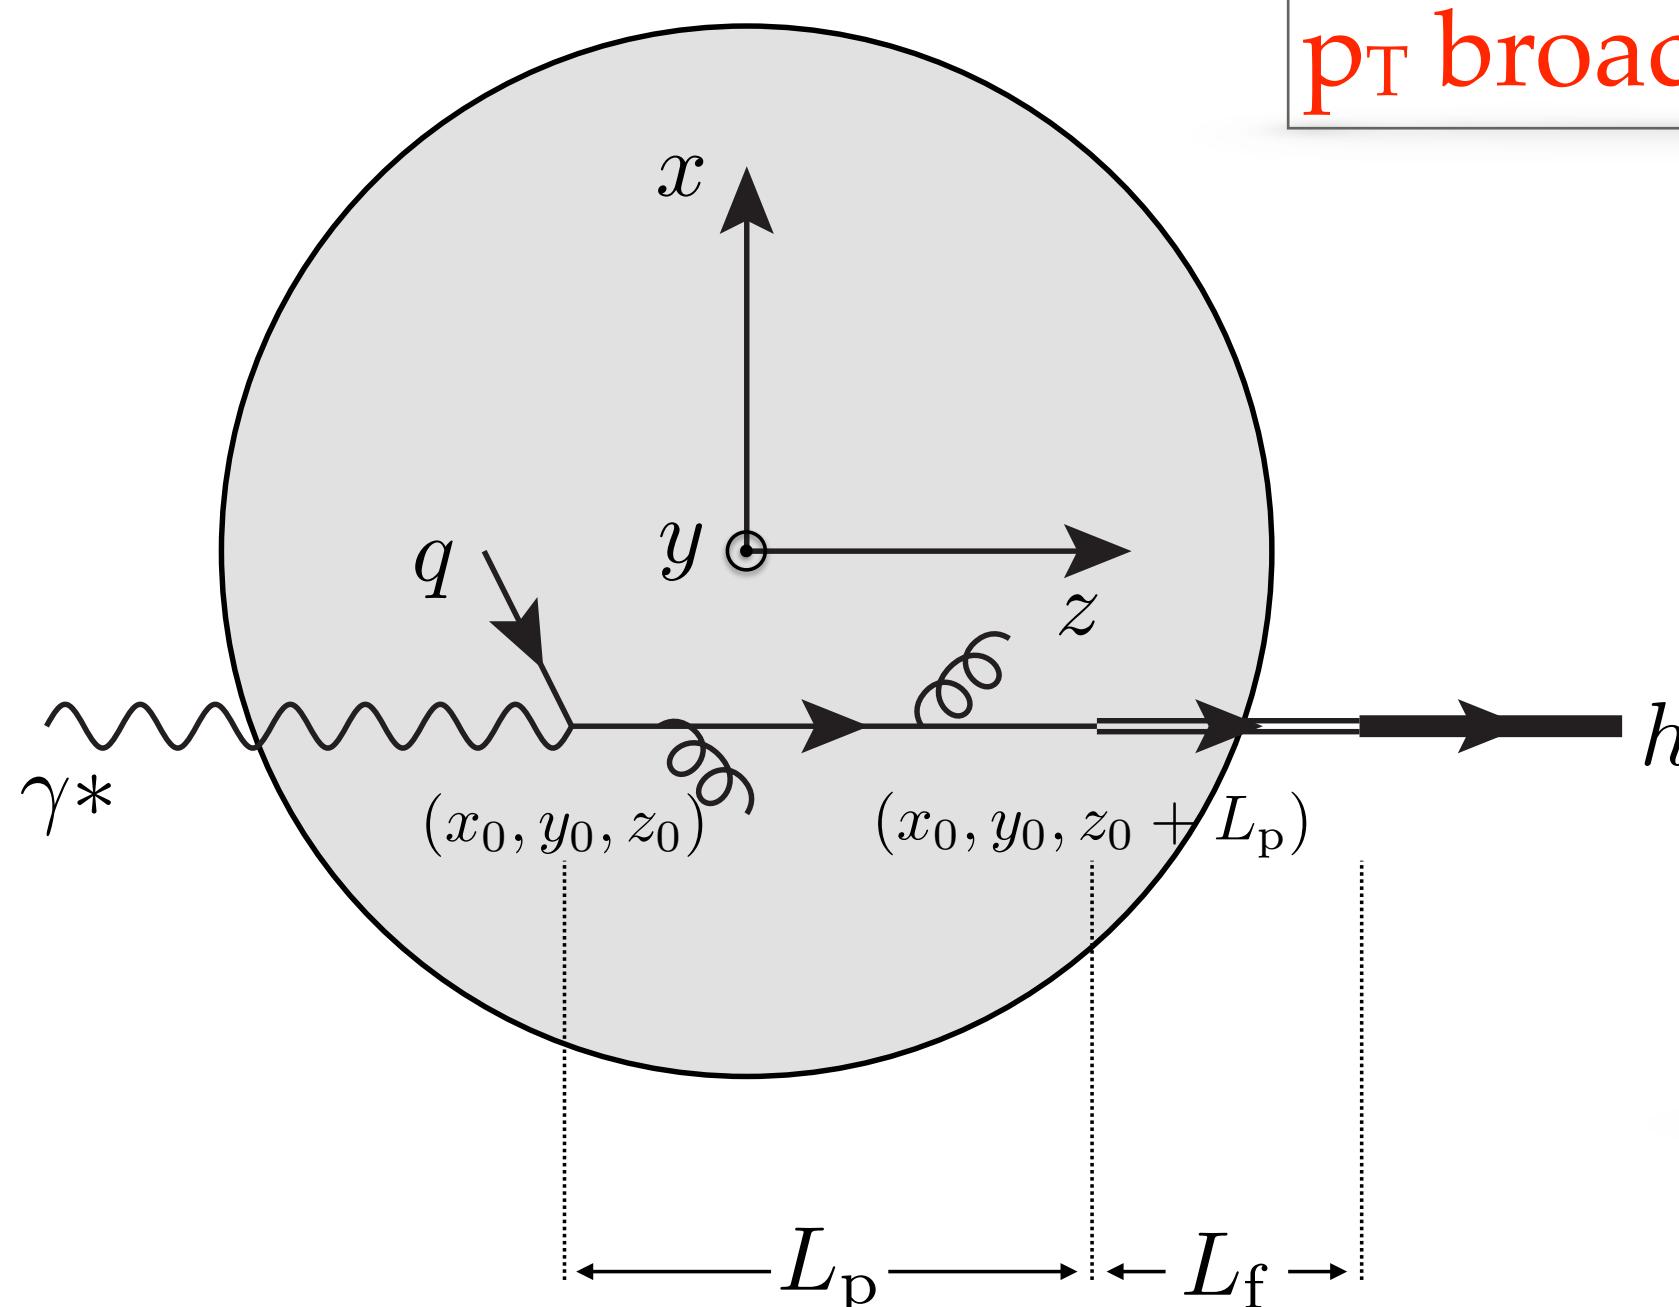

Division of the process into *partonic* and *hadronic* stages

Path of (struck) quark is divided into
“*partonic phase*” and “*hadronic phase*”

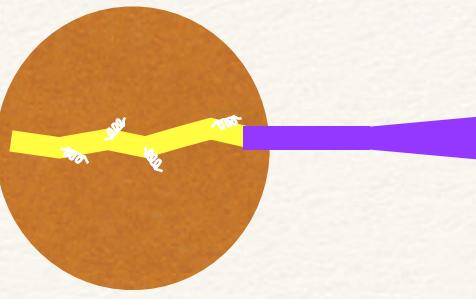

The *partonic phase* persists for a distance L_c , over which p_T broadening via \hat{q} , and partonic energy loss ΔE_q , occur

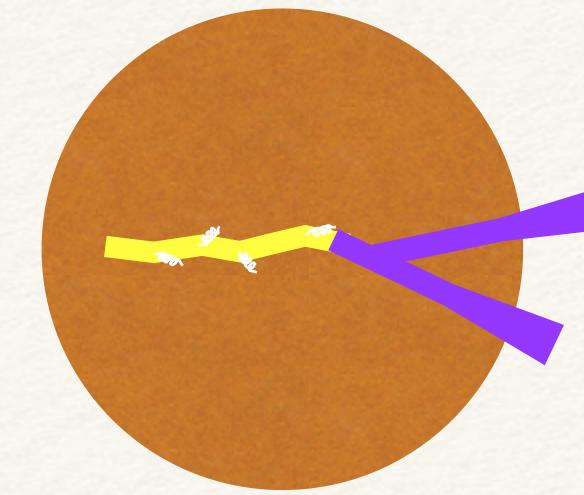

The *hadronic phase* follows the *partonic phase*, passing through the remainder of the medium, and causing attenuation of hadrons by an *inelastic interaction cross section* σ_{inel}

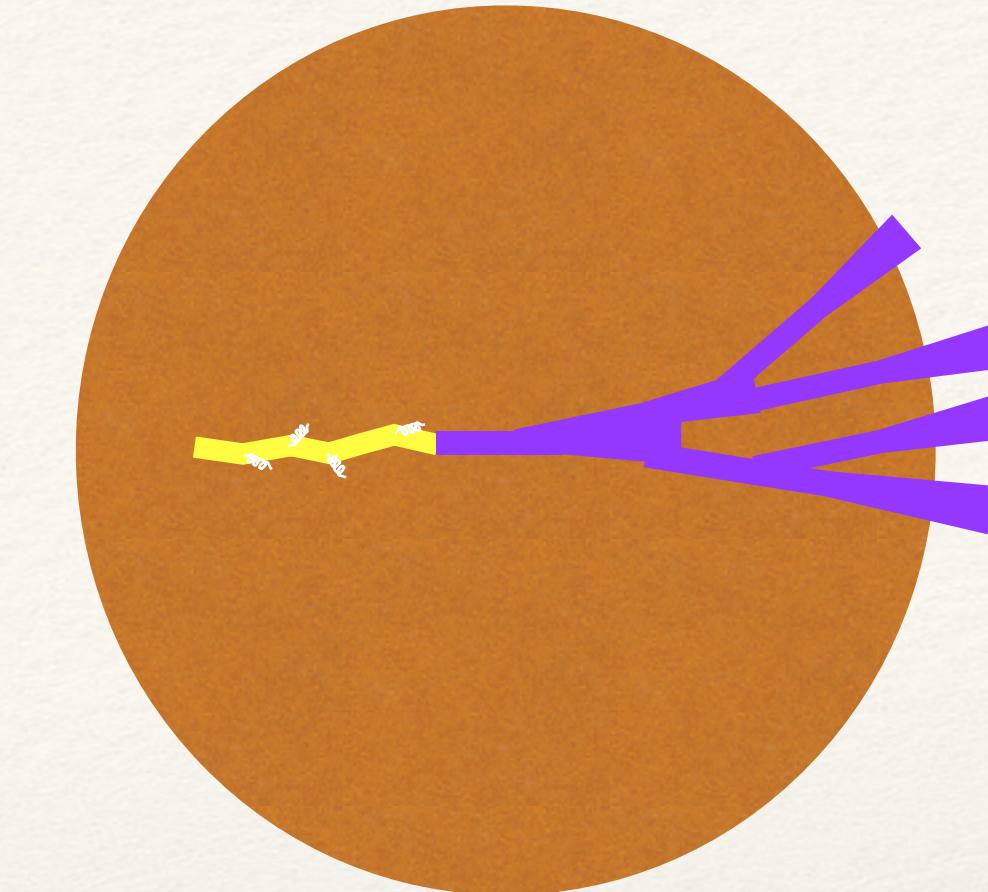

Short color lifetime

Carbon nucleus
Radius = 2.5 fm

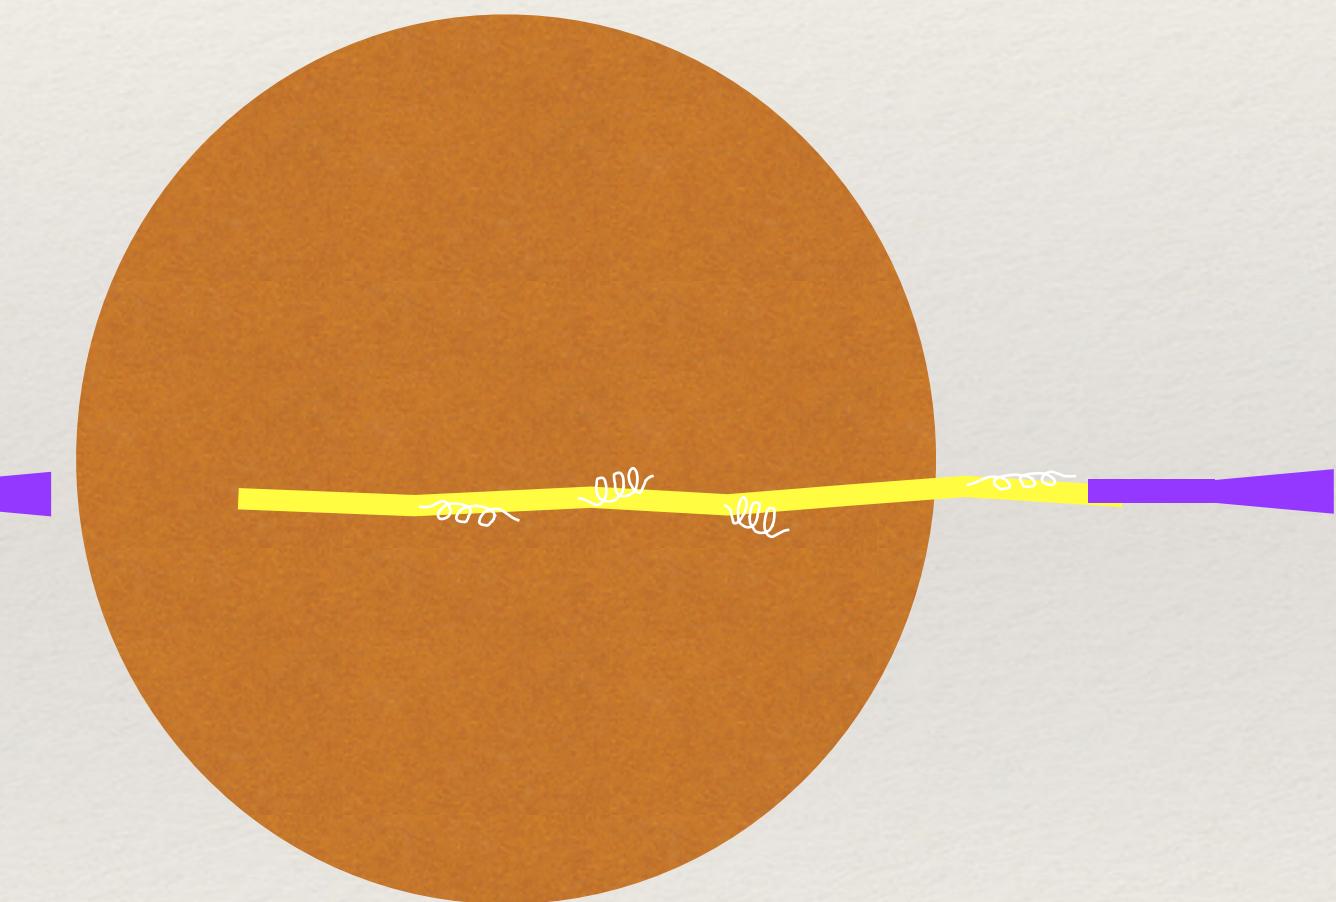

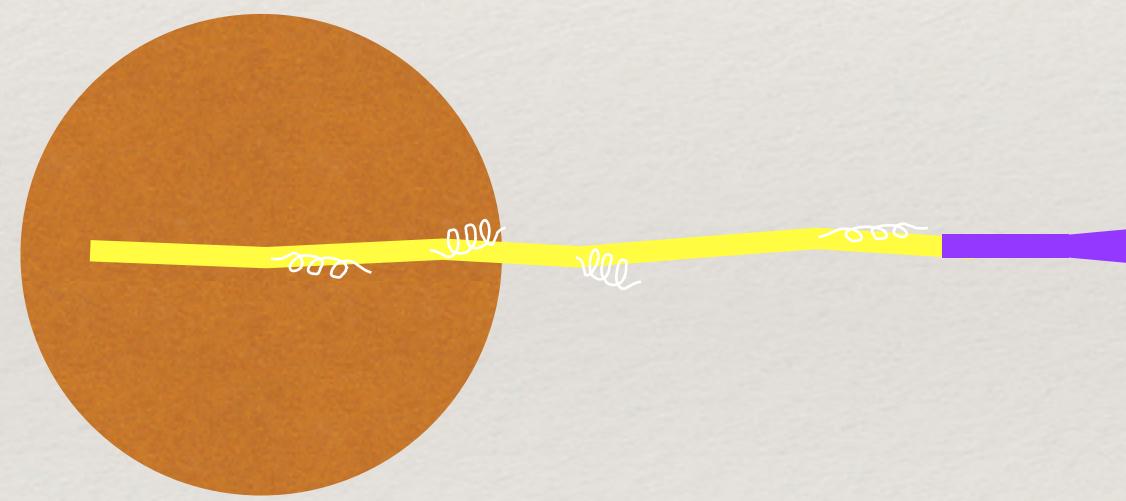

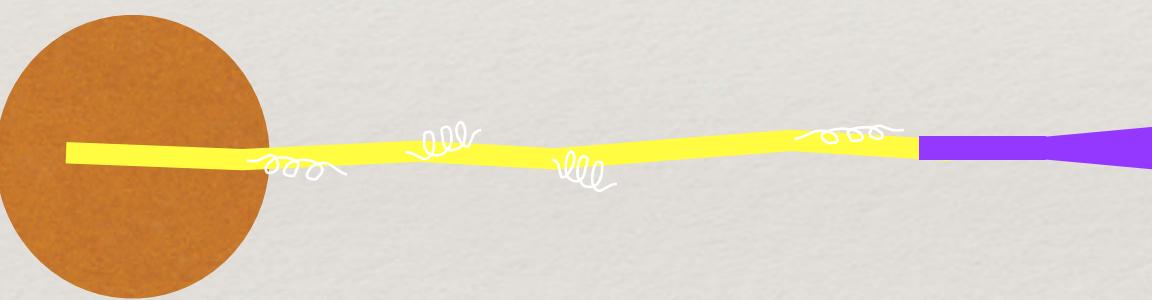

Iron nucleus
Radius = 4.2 fm

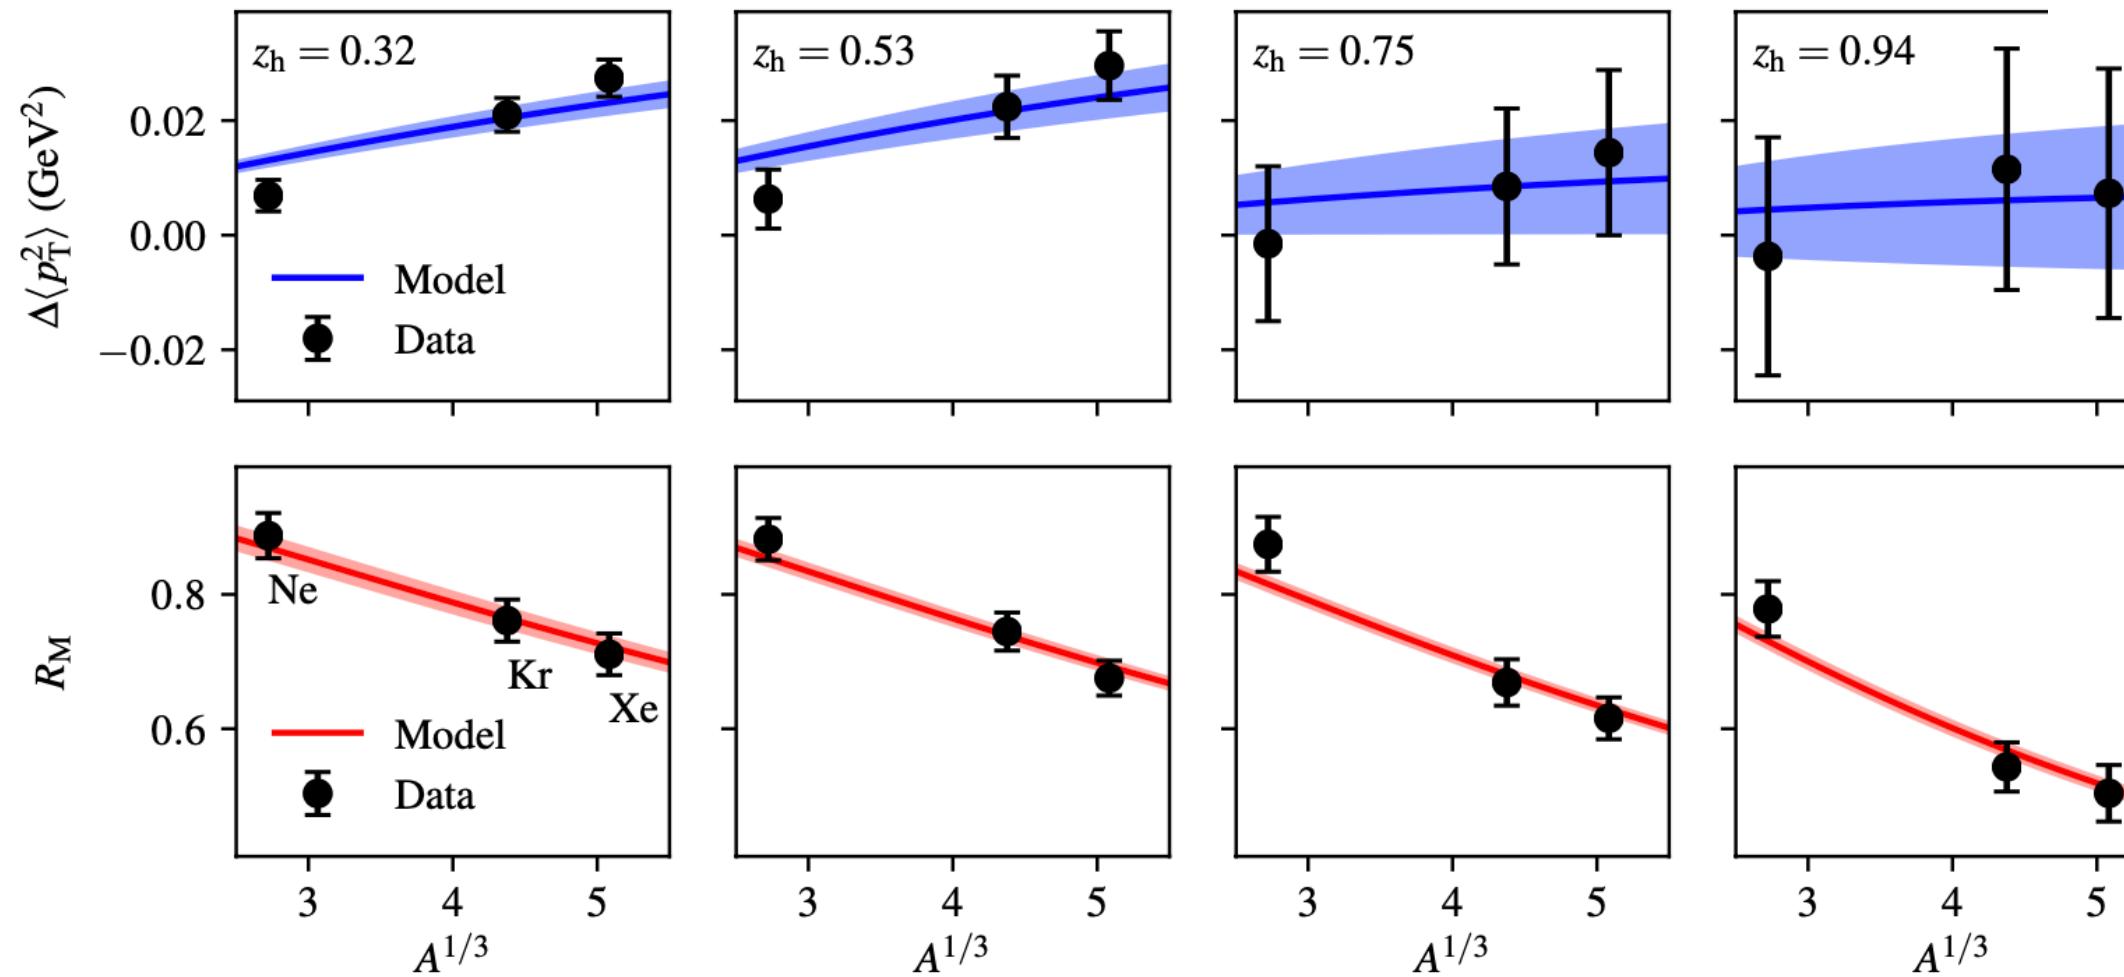

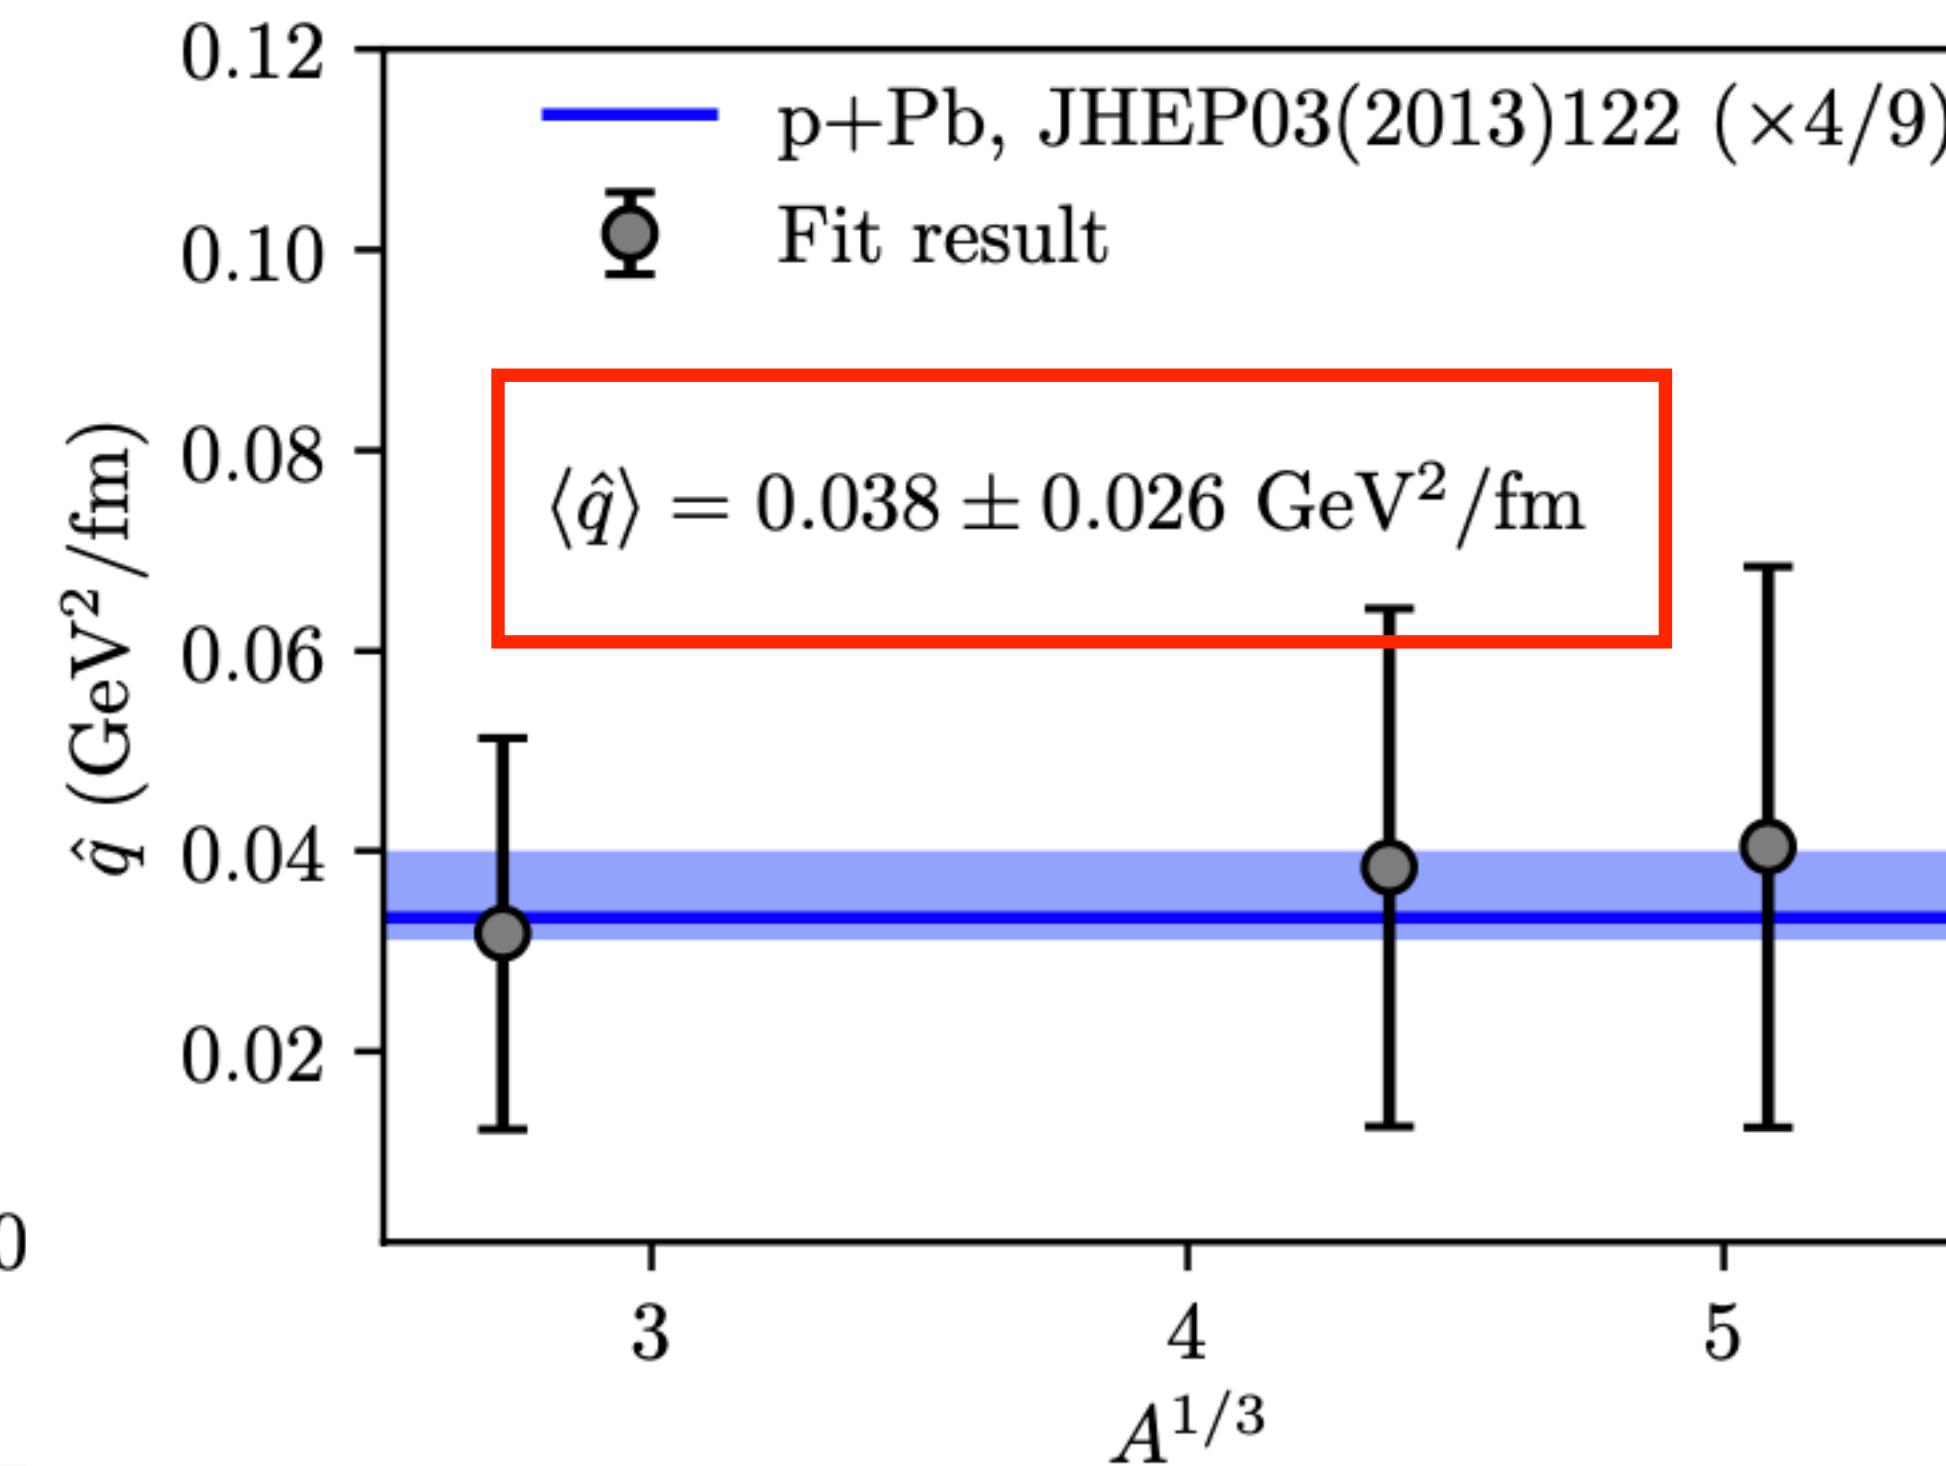

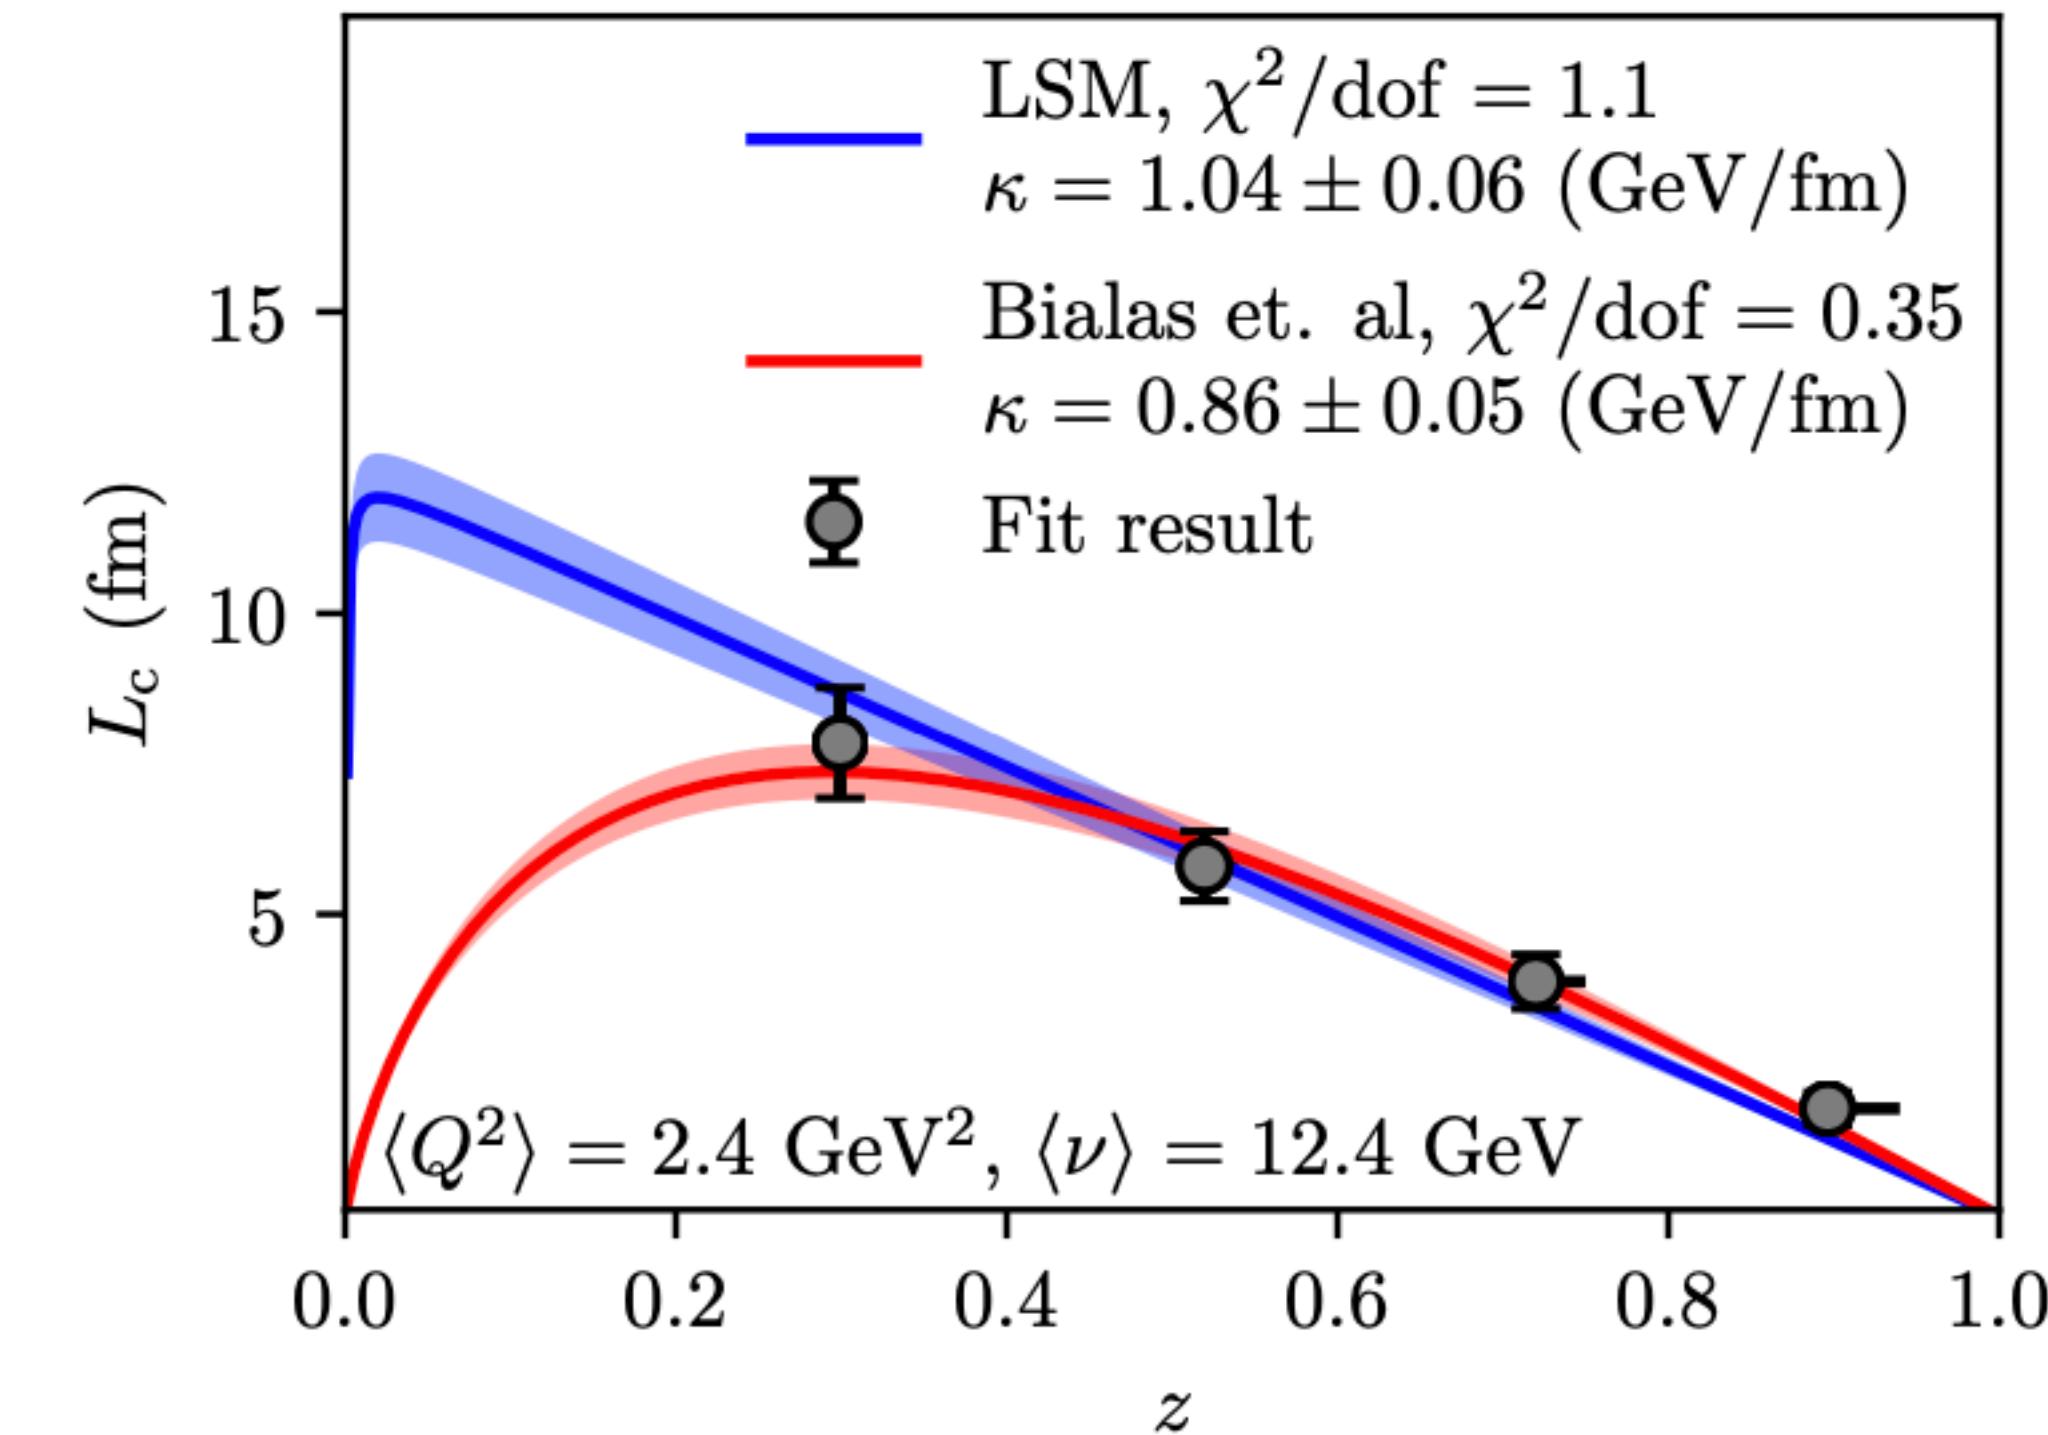

Lead nucleus
Radius = 6.5 fm

Long color lifetime

By comparing p_T broadening and hadron attenuation in nuclei of different sizes, one can measure the *length* of the color propagation process (femtometer scale)

Recent fit to
HERMES data
validates this
physical picture

Model Variant	Free parameters	χ^2/dof of fit to data vs. z_h				Fit of results to LSM analytical forms	
		0.32	0.53	0.75	0.94	Analytical form	κ (GeV/fm)
Baseline Model with fixed hadronic cross-section	2	1.8	1.1	0.7	0.5	struck quark	1.04 ± 0.06

						B&G	1.09 ± 0.08

Independently reproduces
the Lund String Model
string constant!

Simultaneous fit to multiplicity ratio and p_T broadening
Brooks and López, <https://arxiv.org/abs/2004.07236>

What can CLAS+CLAS12 add to these studies?

Much more luminosity than HERMES

- As a result, can study **rare and/or complex** states: ω meson, η meson, Λ baryon (now) and ϕ meson, η' meson, Σ and Ξ baryons, and more at 12 GeV!
- This will allow to probe mass, strangeness, and rank dependence of hadron formation and color propagation. This is **terra incognita!**
- **New motivation** for studying baryons with these observables: new ideas that may reveal model-independent view of diquark degrees of freedom for neutrons, protons and lambdas. **New baryon structure information** from nuclear target experiments!

CLAS and CLAS12 Color Propagation Hadrons

Actively underway with existing 5 GeV data

Selected results from CLAS6

π^0 3D Multiplicity Ratios

Dr. Taisiya Mineeva, UTFSM

(UConn PhD 2013, K. Joo Thesis Advisor)

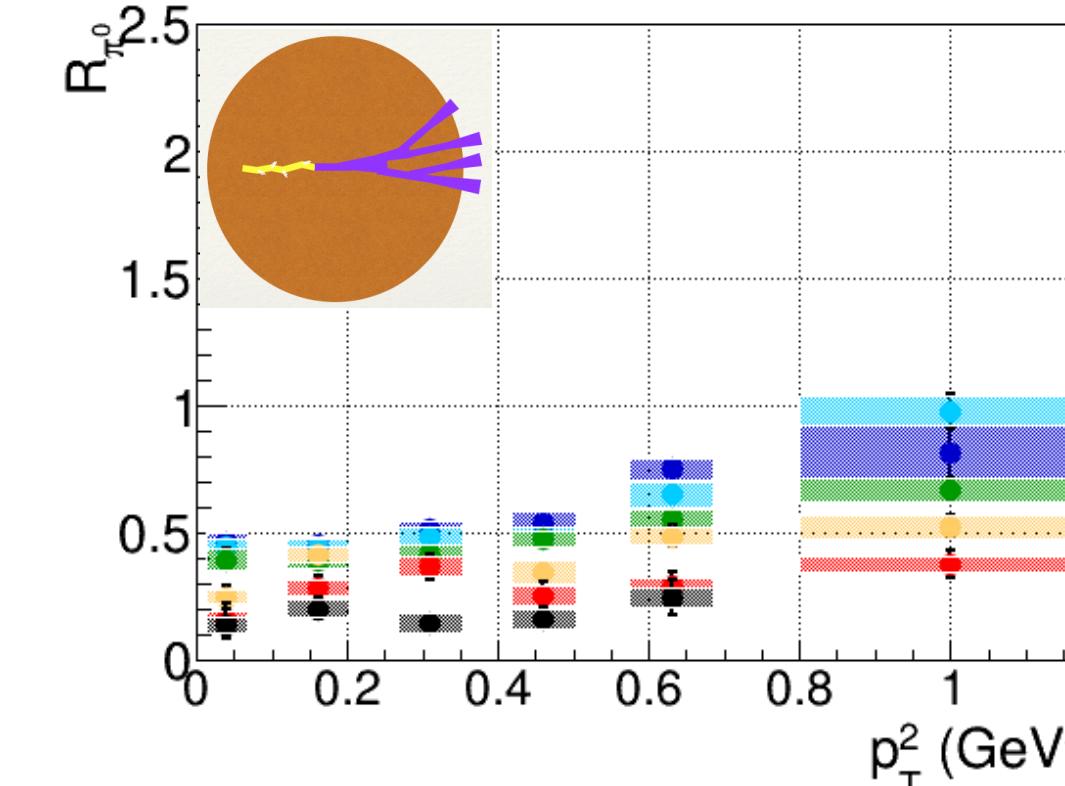

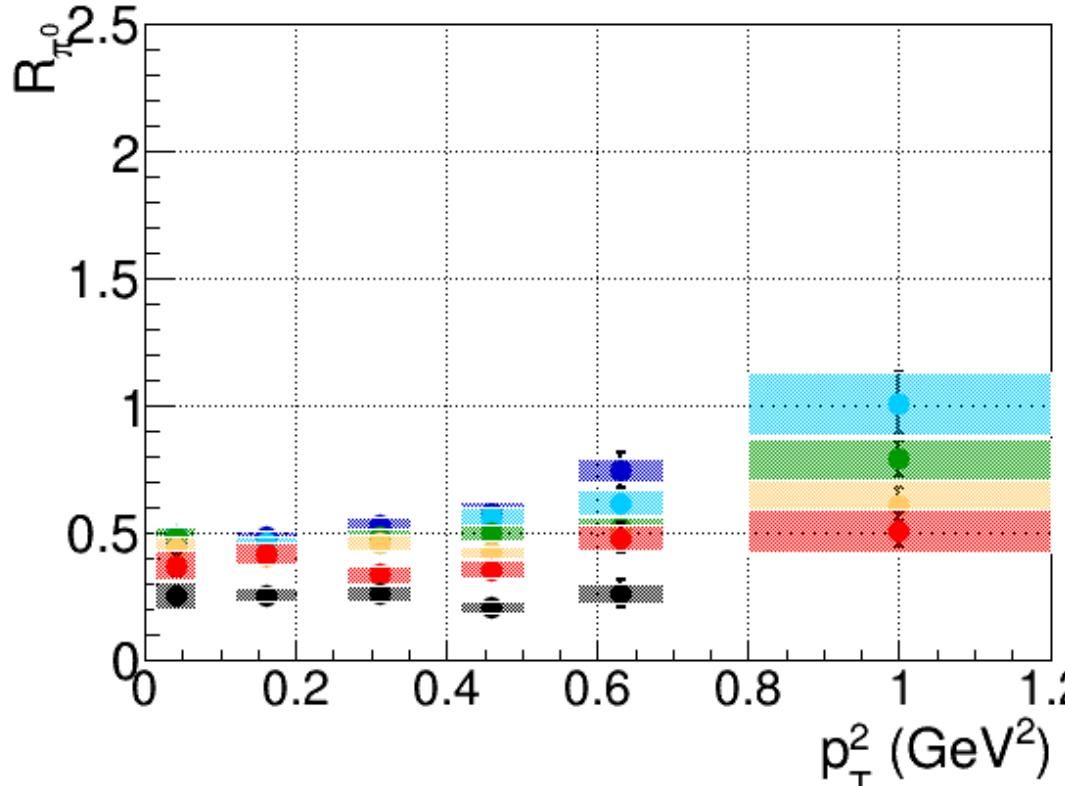

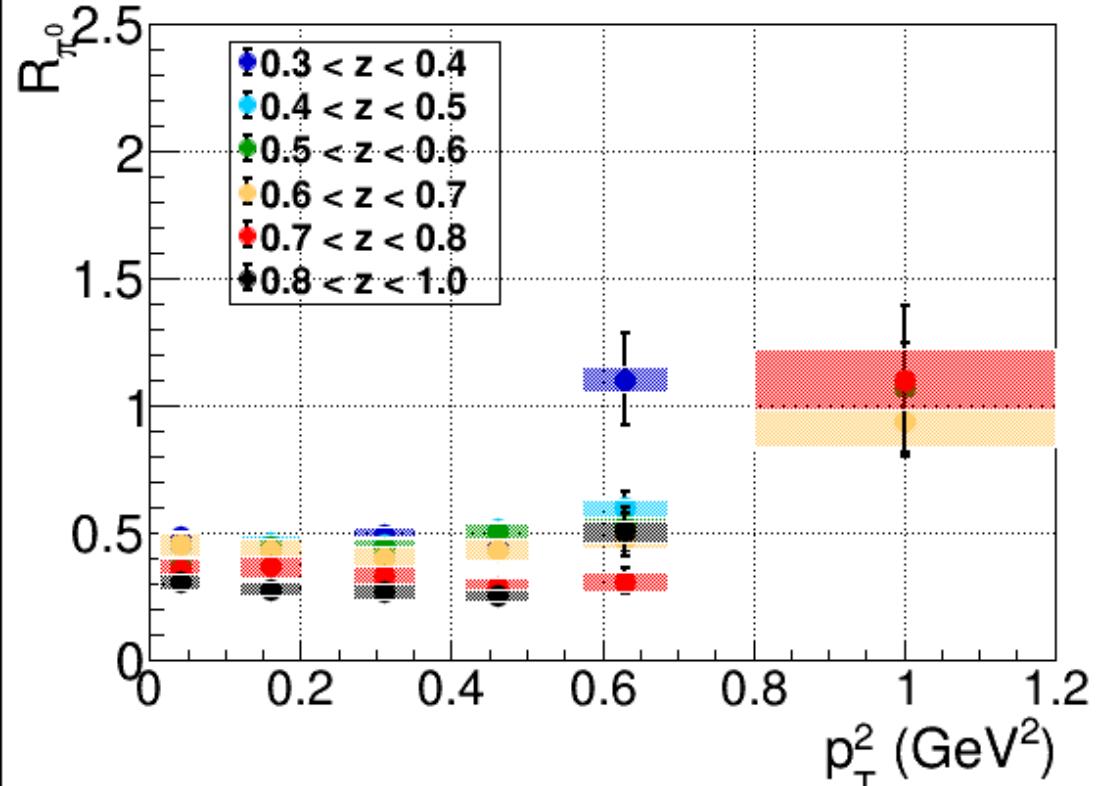

(3rd round of analysis review completed)

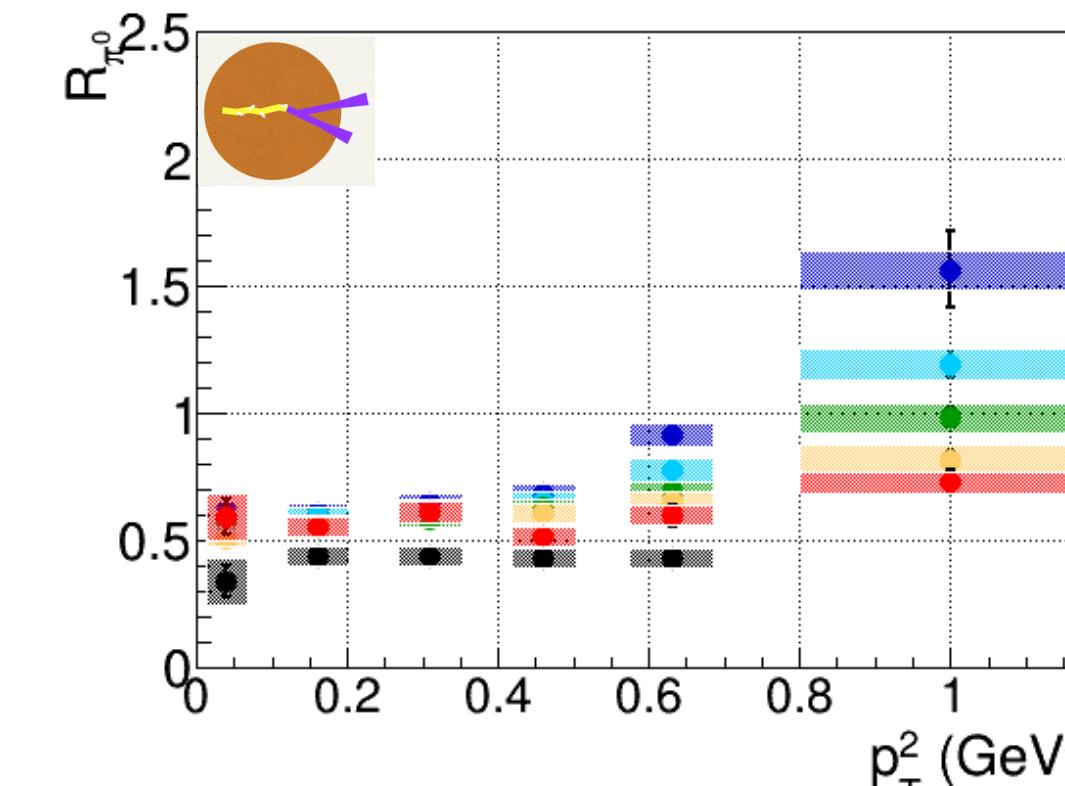

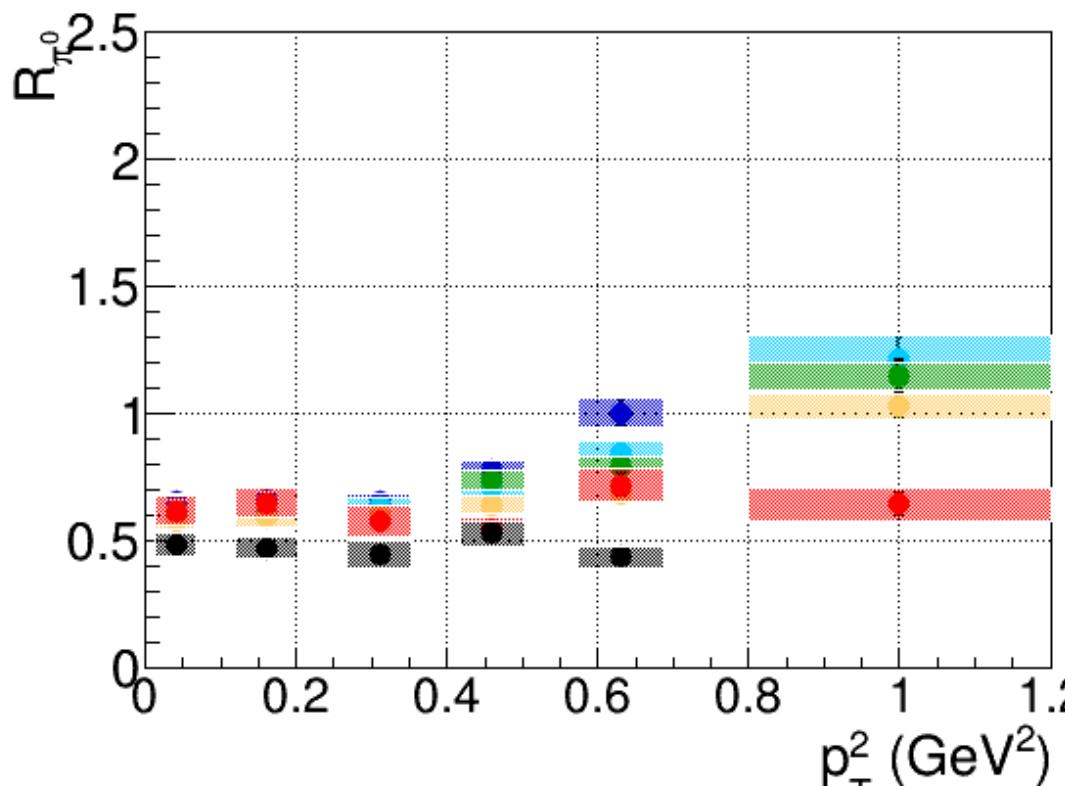

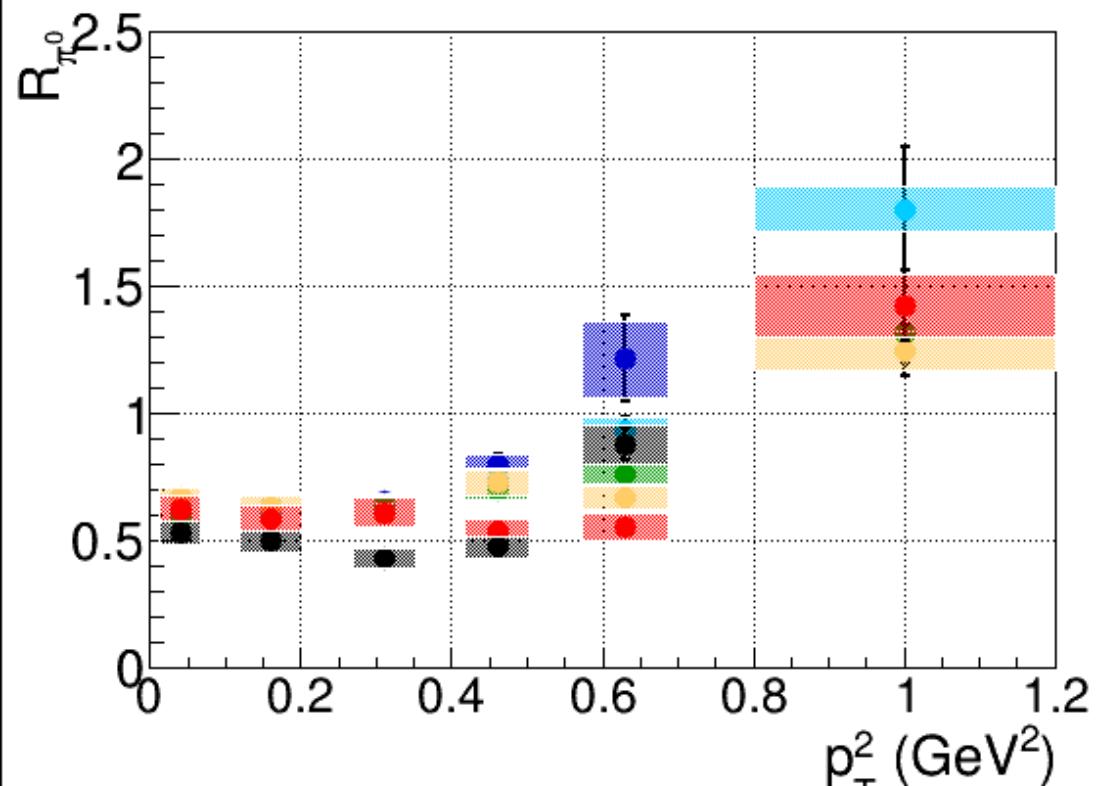

Note: almost 80% of the neutral pions “disappear” from the high z bin in Pb!
This is a dramatically strong interaction.
Even at low z , half of them are still “missing.”

π^0 3D MR (continued), Dr. Taisiya Mineeva, UTFSM

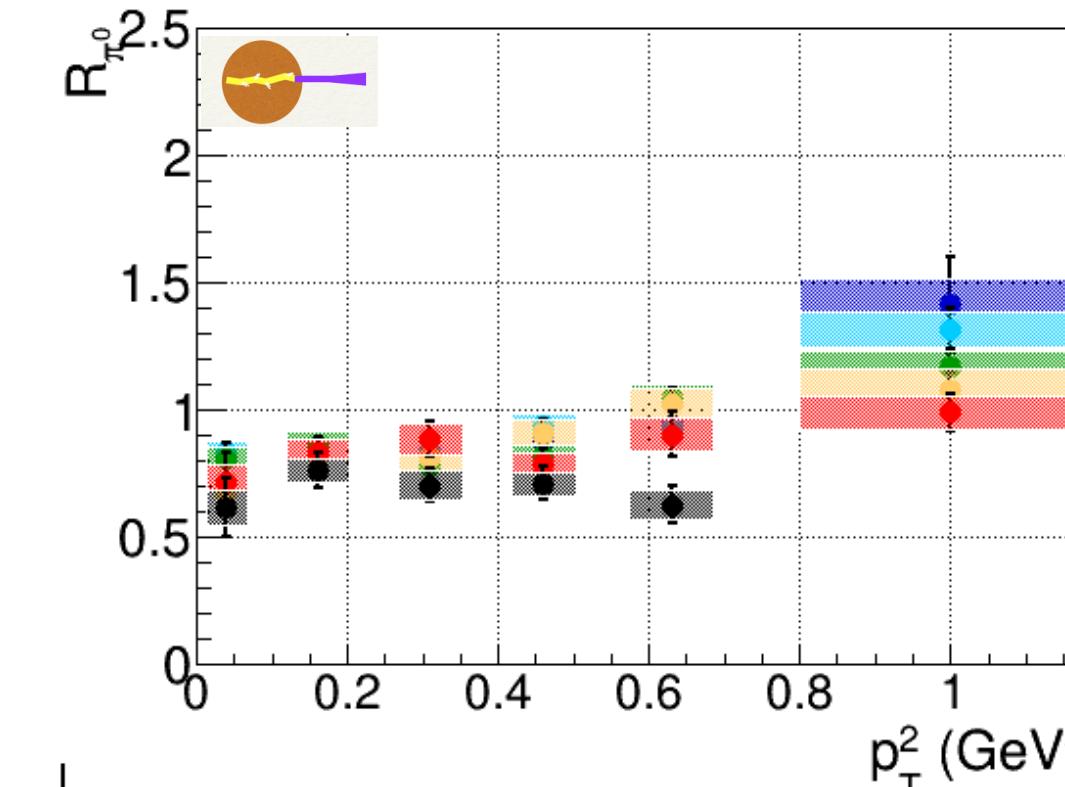

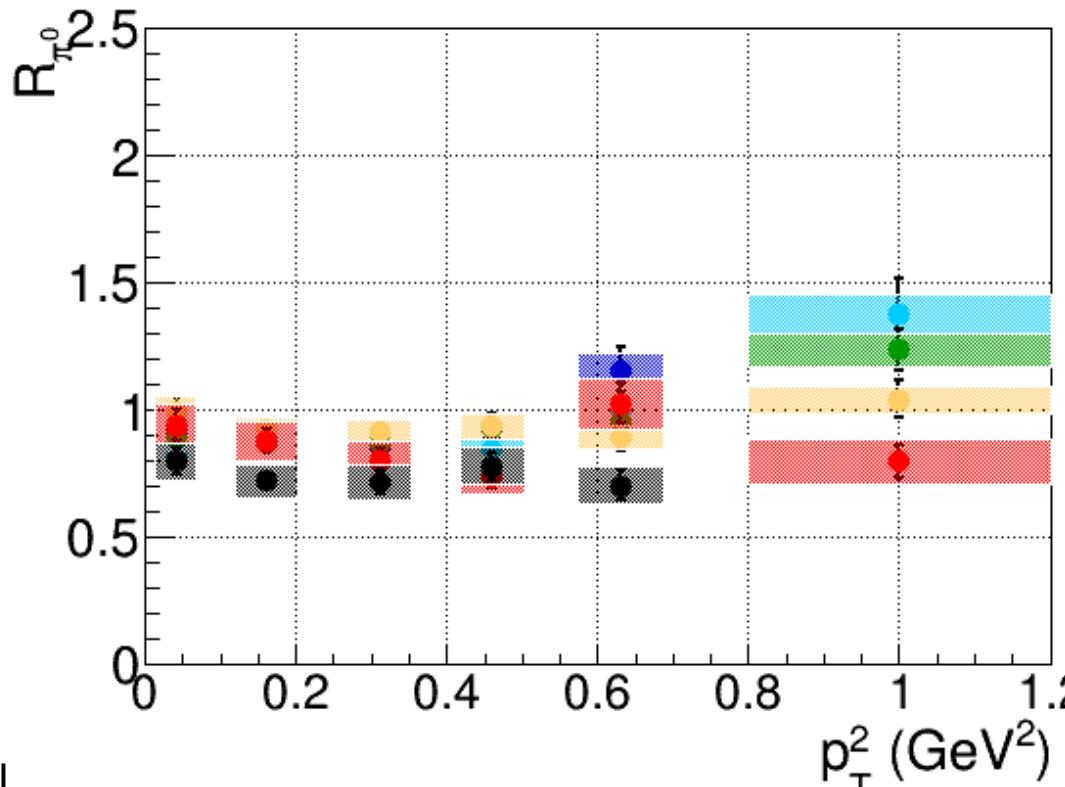

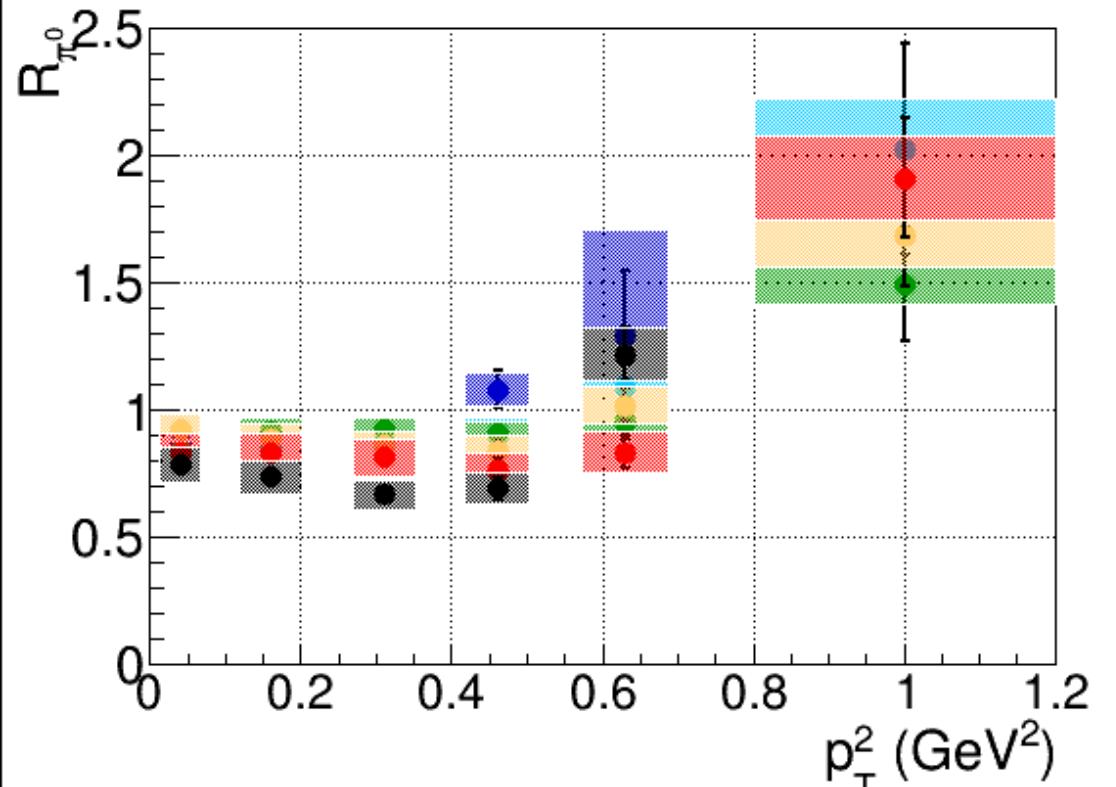

Pb

Fe

C

2.20

3.20

3.73

4.25

Neutral pion 3D MR

Cronin-like enhancement at high p_T as expected, NOT SEEN by HERMES due to insufficient statistics.

Regular z-ordering at high v and high p_T , especially for lower-A, consistent with a few-fm average color lifetime that goes to zero at high z as expected.

Eta Meson Multiplicity Ratios

Dr. Orlando Soto, INFN Frascati

- PhD thesis topic from UTFSM, 2018 (Prof. Hayk Hakobyan, thesis advisor)
- A **world's first measurement** of nuclear DIS production of eta mesons
 - Limited statistics in this pioneering work; will be much better in CLAS12
- **Performed in 2 decay channels**
 - Cross-check for consistency; decay channel dependence not anticipated due to $c\tau \approx 170$ pm lifetime of eta meson

Multiplicity Ratio without background subtraction.

(Shows statistical information quality)

The two decay channels are not consistent without background subtraction.

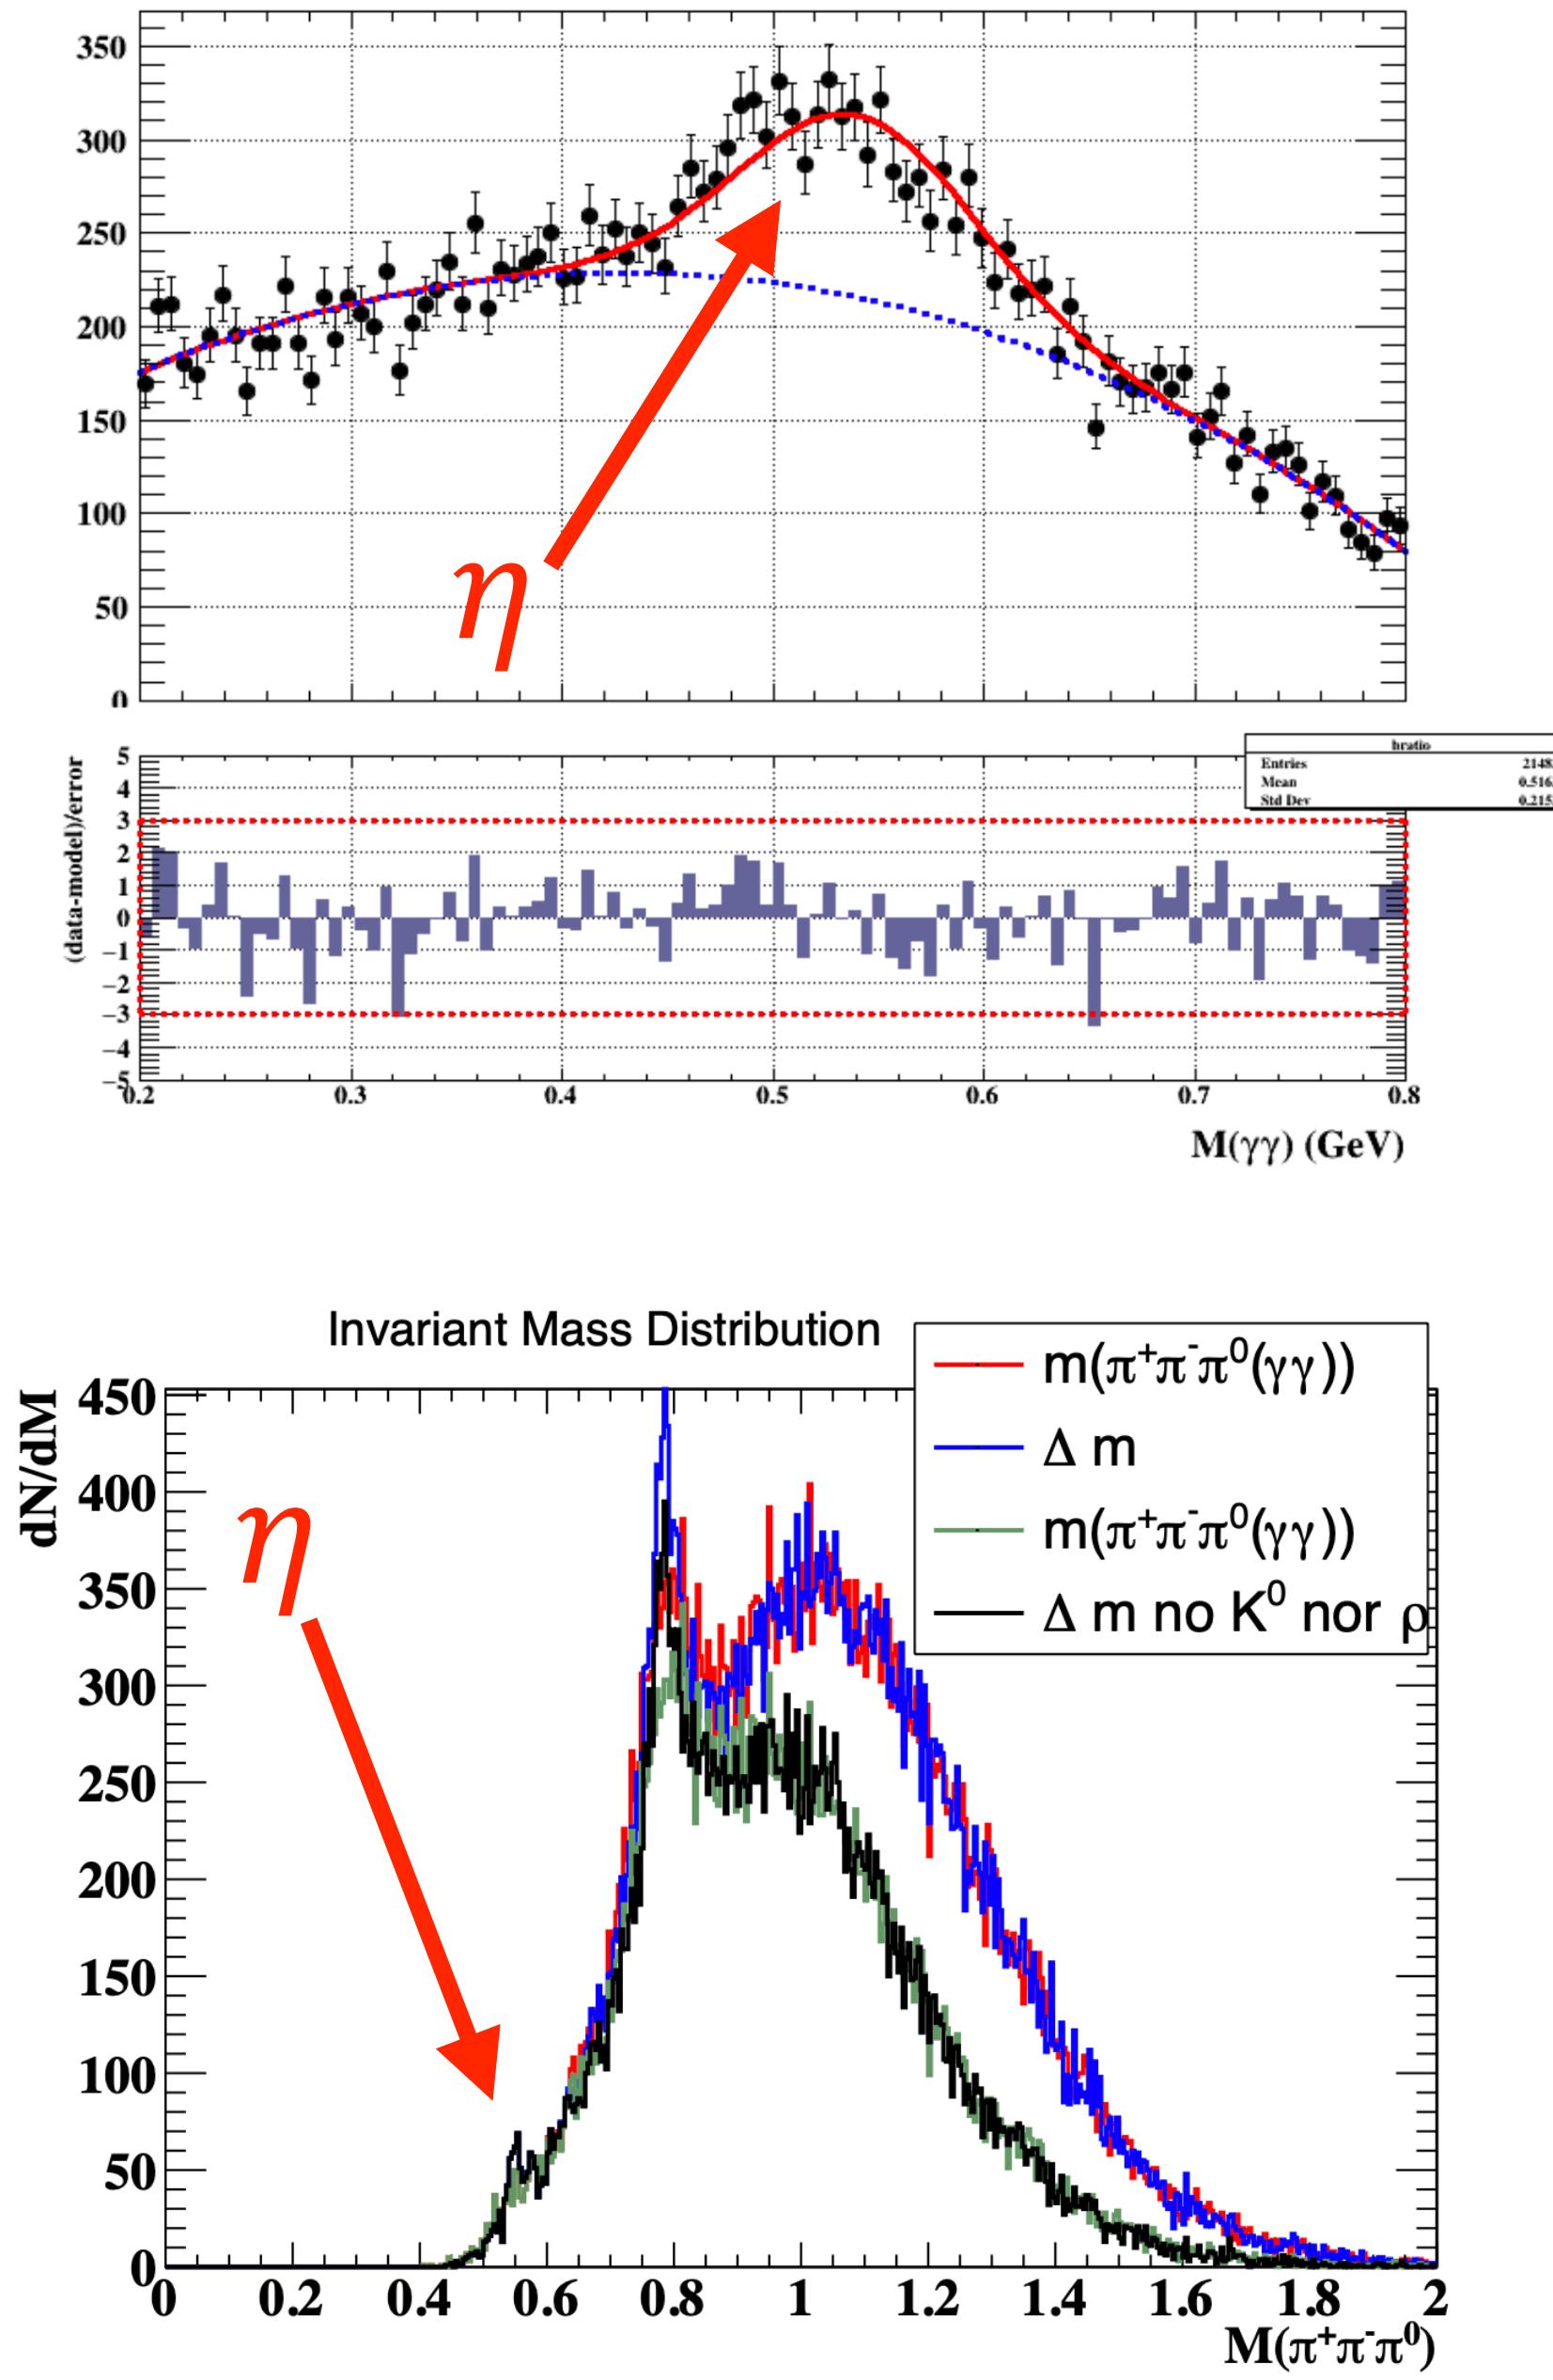

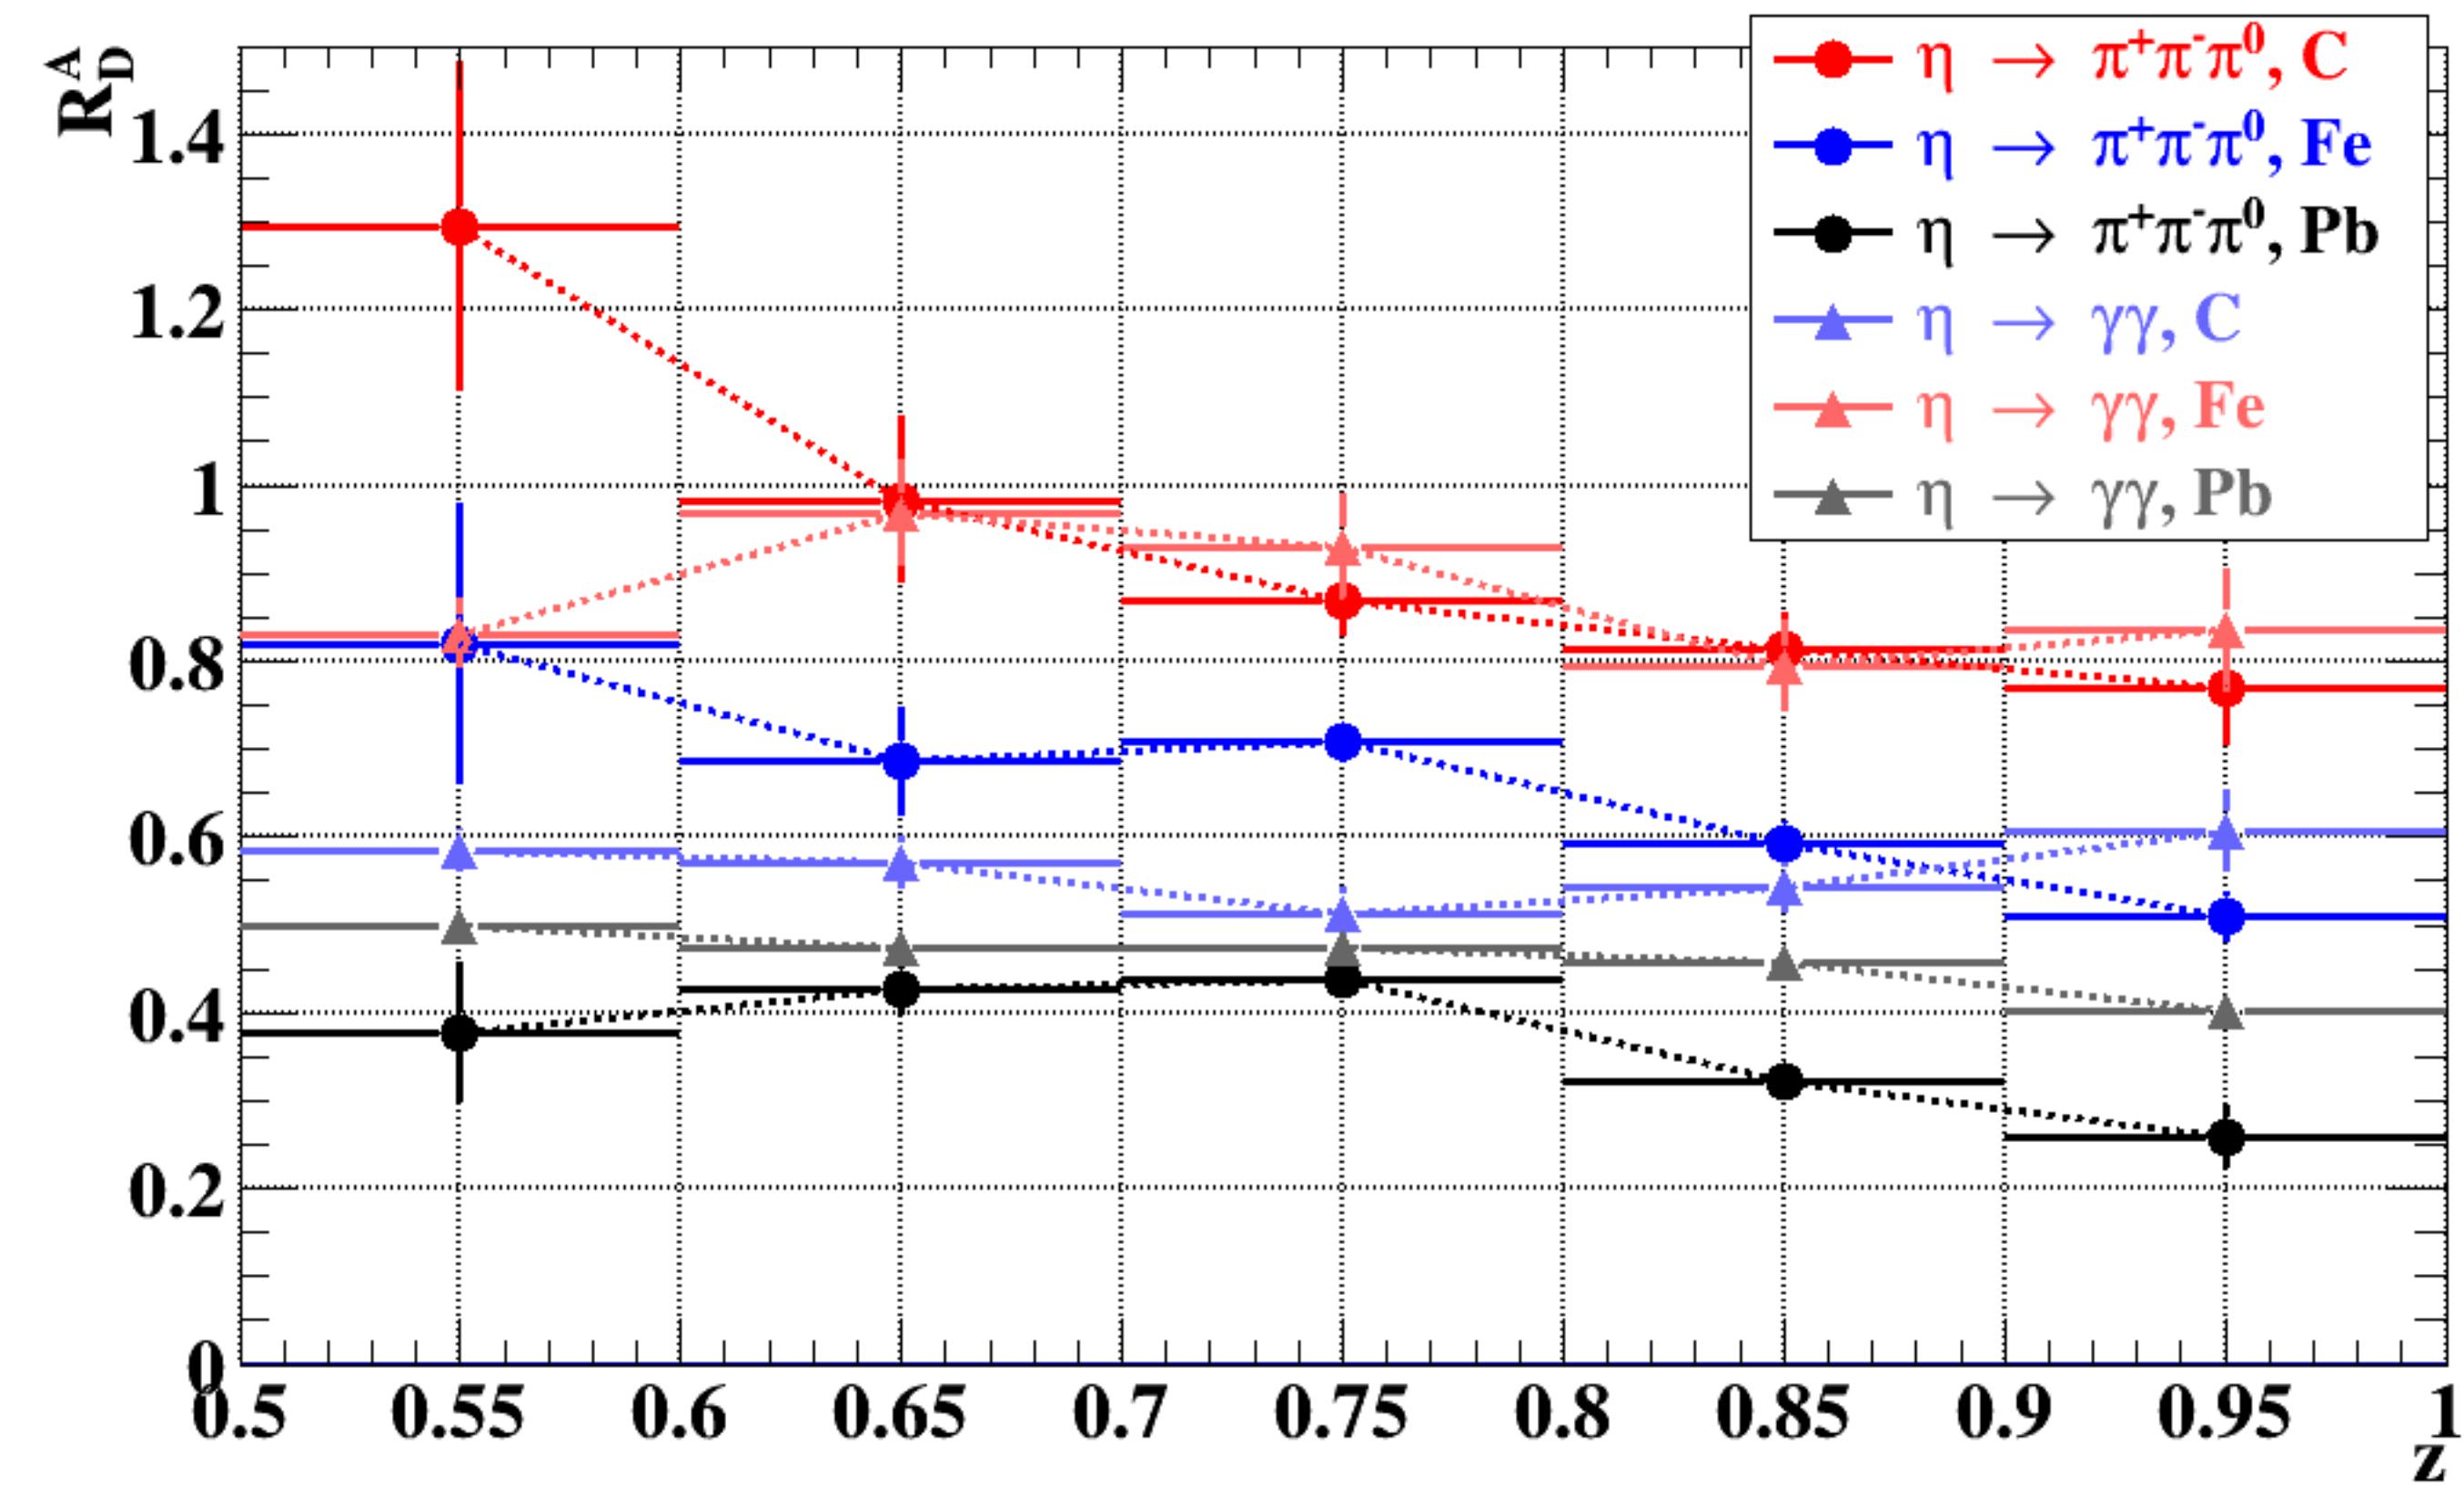

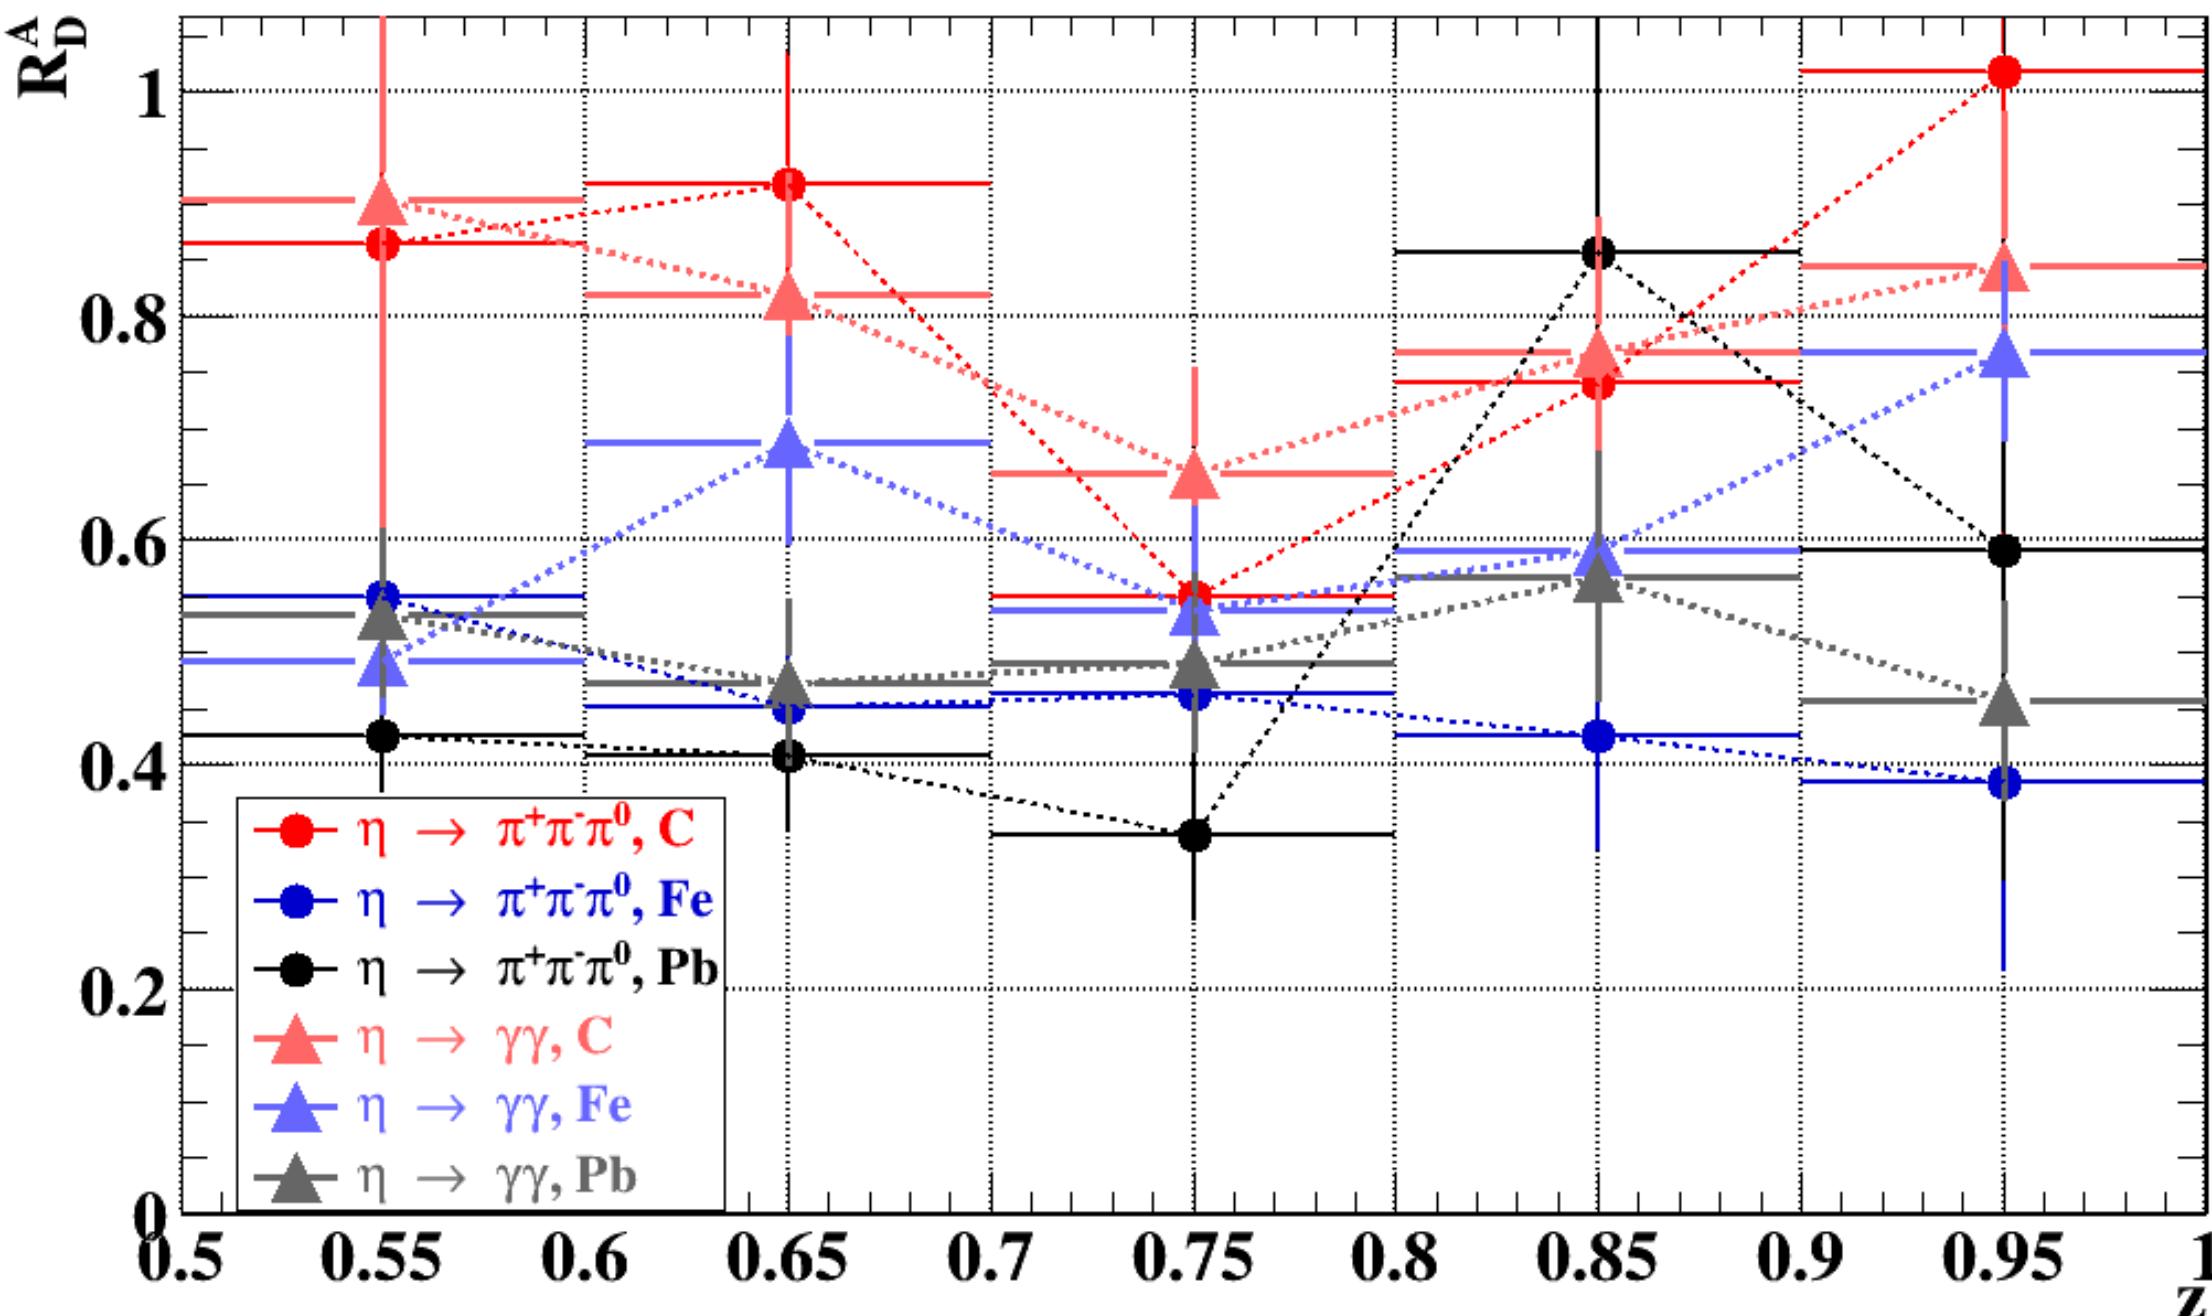

Figure 3.23: Invariant mass $m(\pi^+, \pi^-, \gamma, \gamma)$ with a cut $0.1 < m(\gamma, \gamma) < 0.2$.

Multiplicity Ratio, $\eta \rightarrow \pi^+\pi^-\pi^0 / \eta \rightarrow \gamma\gamma$ (no BS)

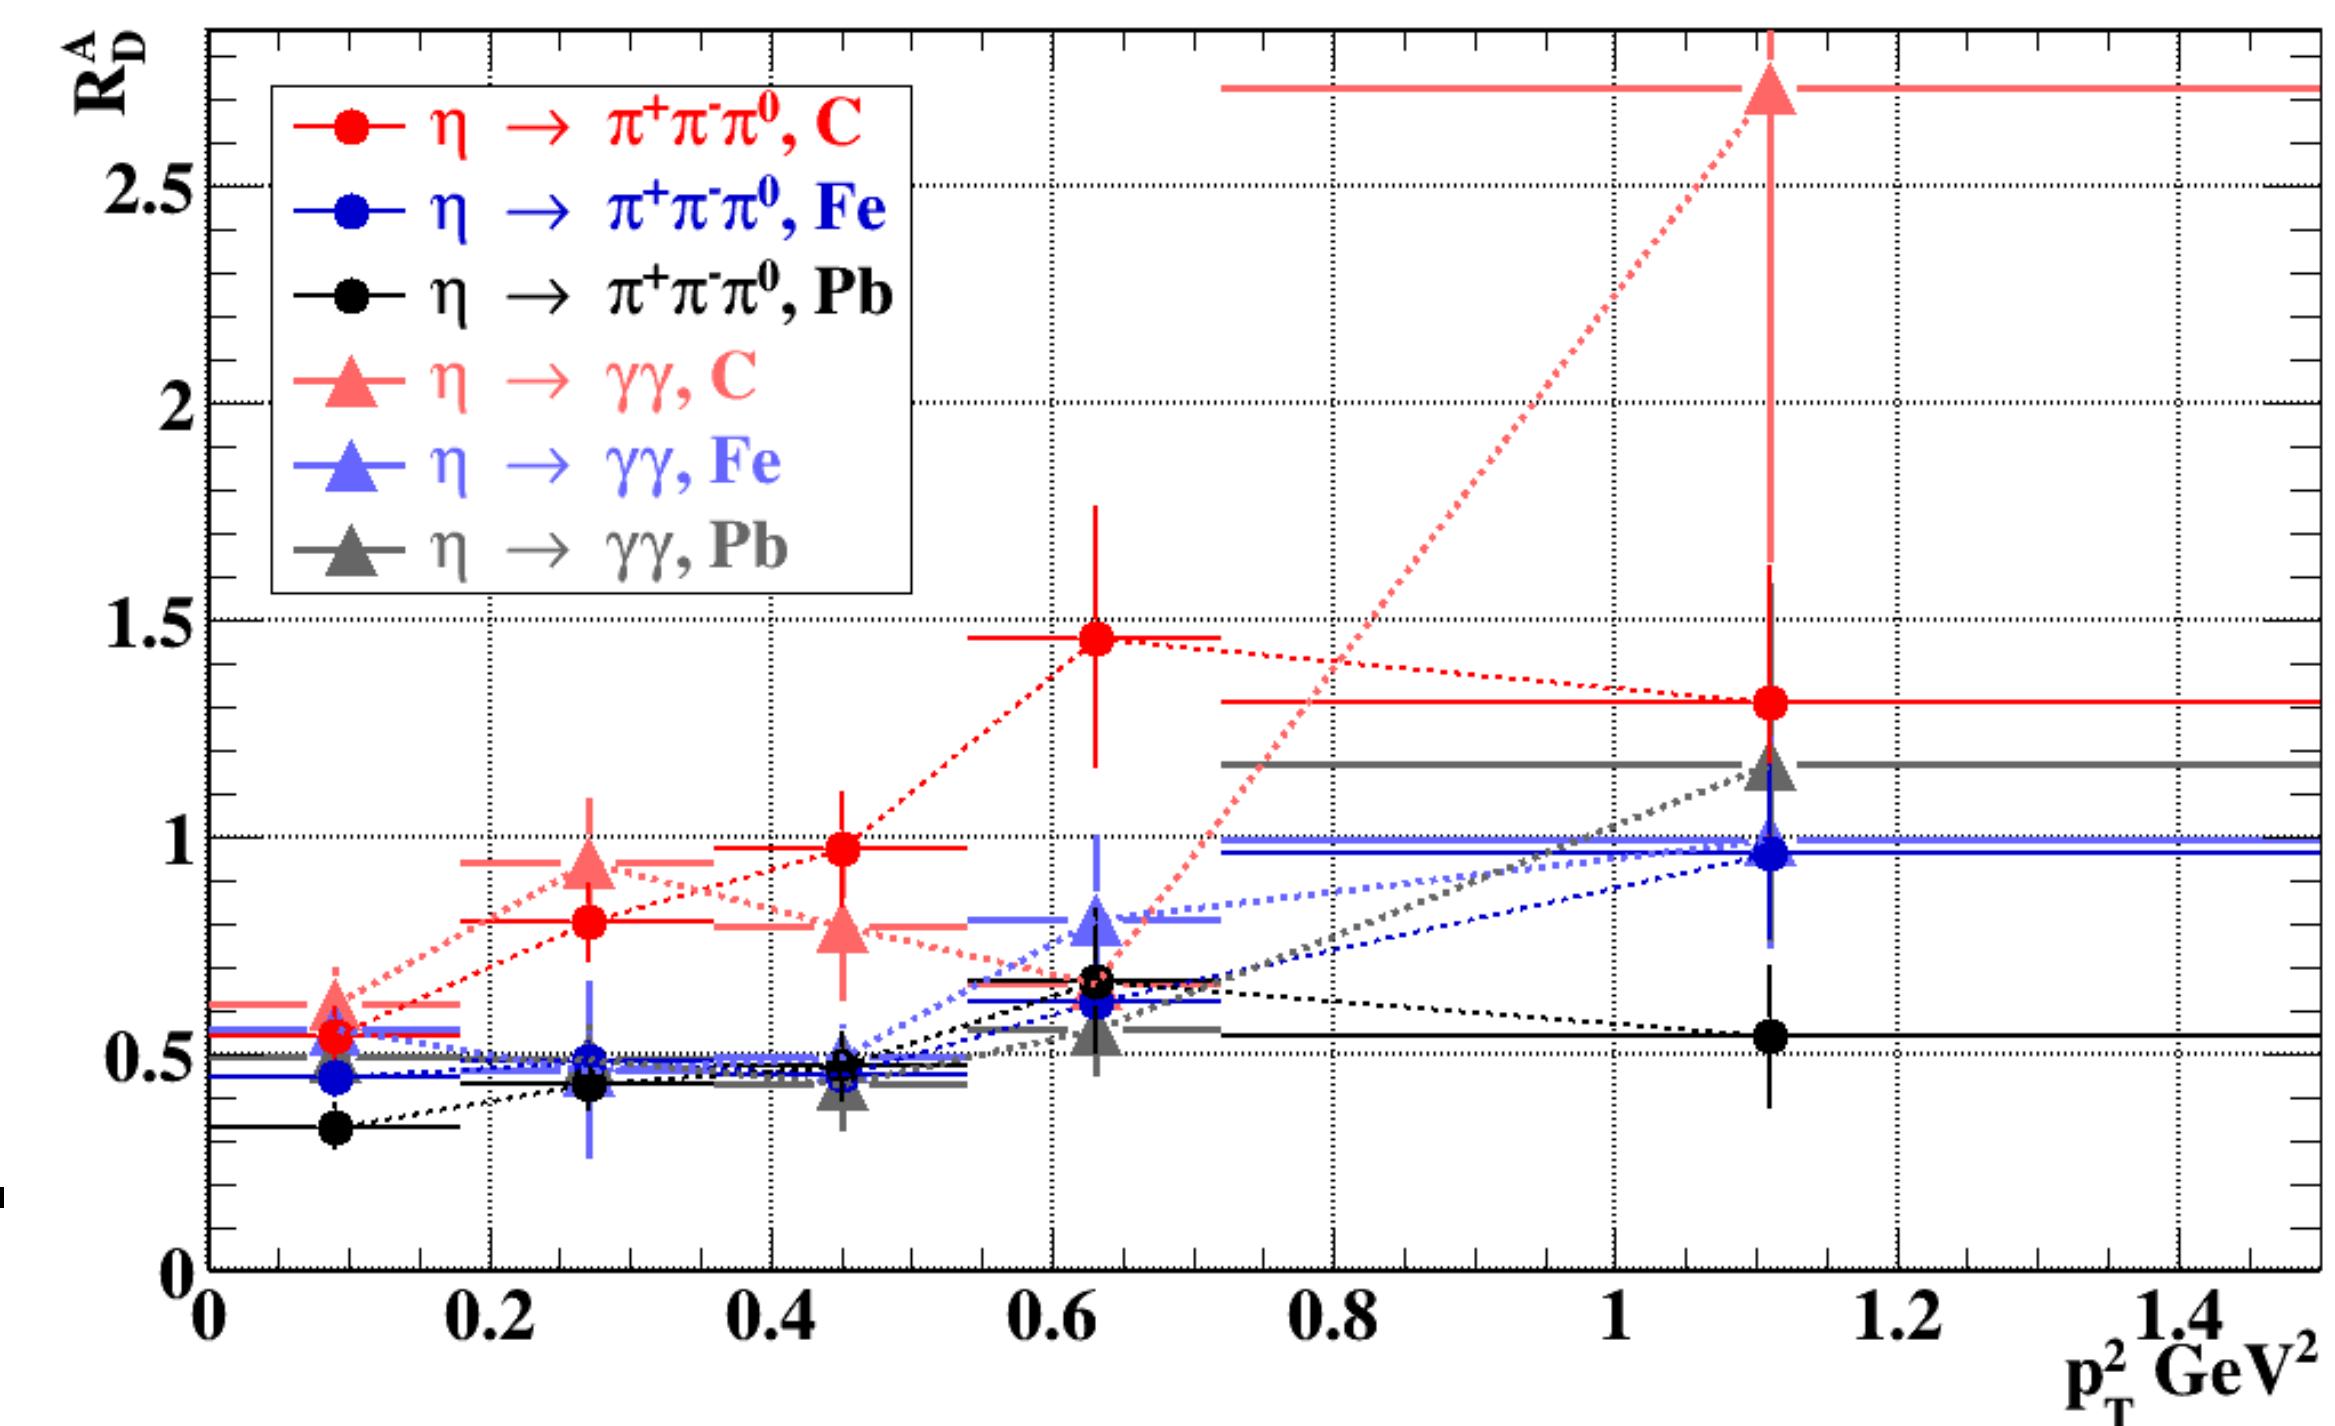

Multiplicity Ratio, $\eta \rightarrow \pi^+\pi^-\pi^0 / \eta \rightarrow \gamma\gamma$ (BS)

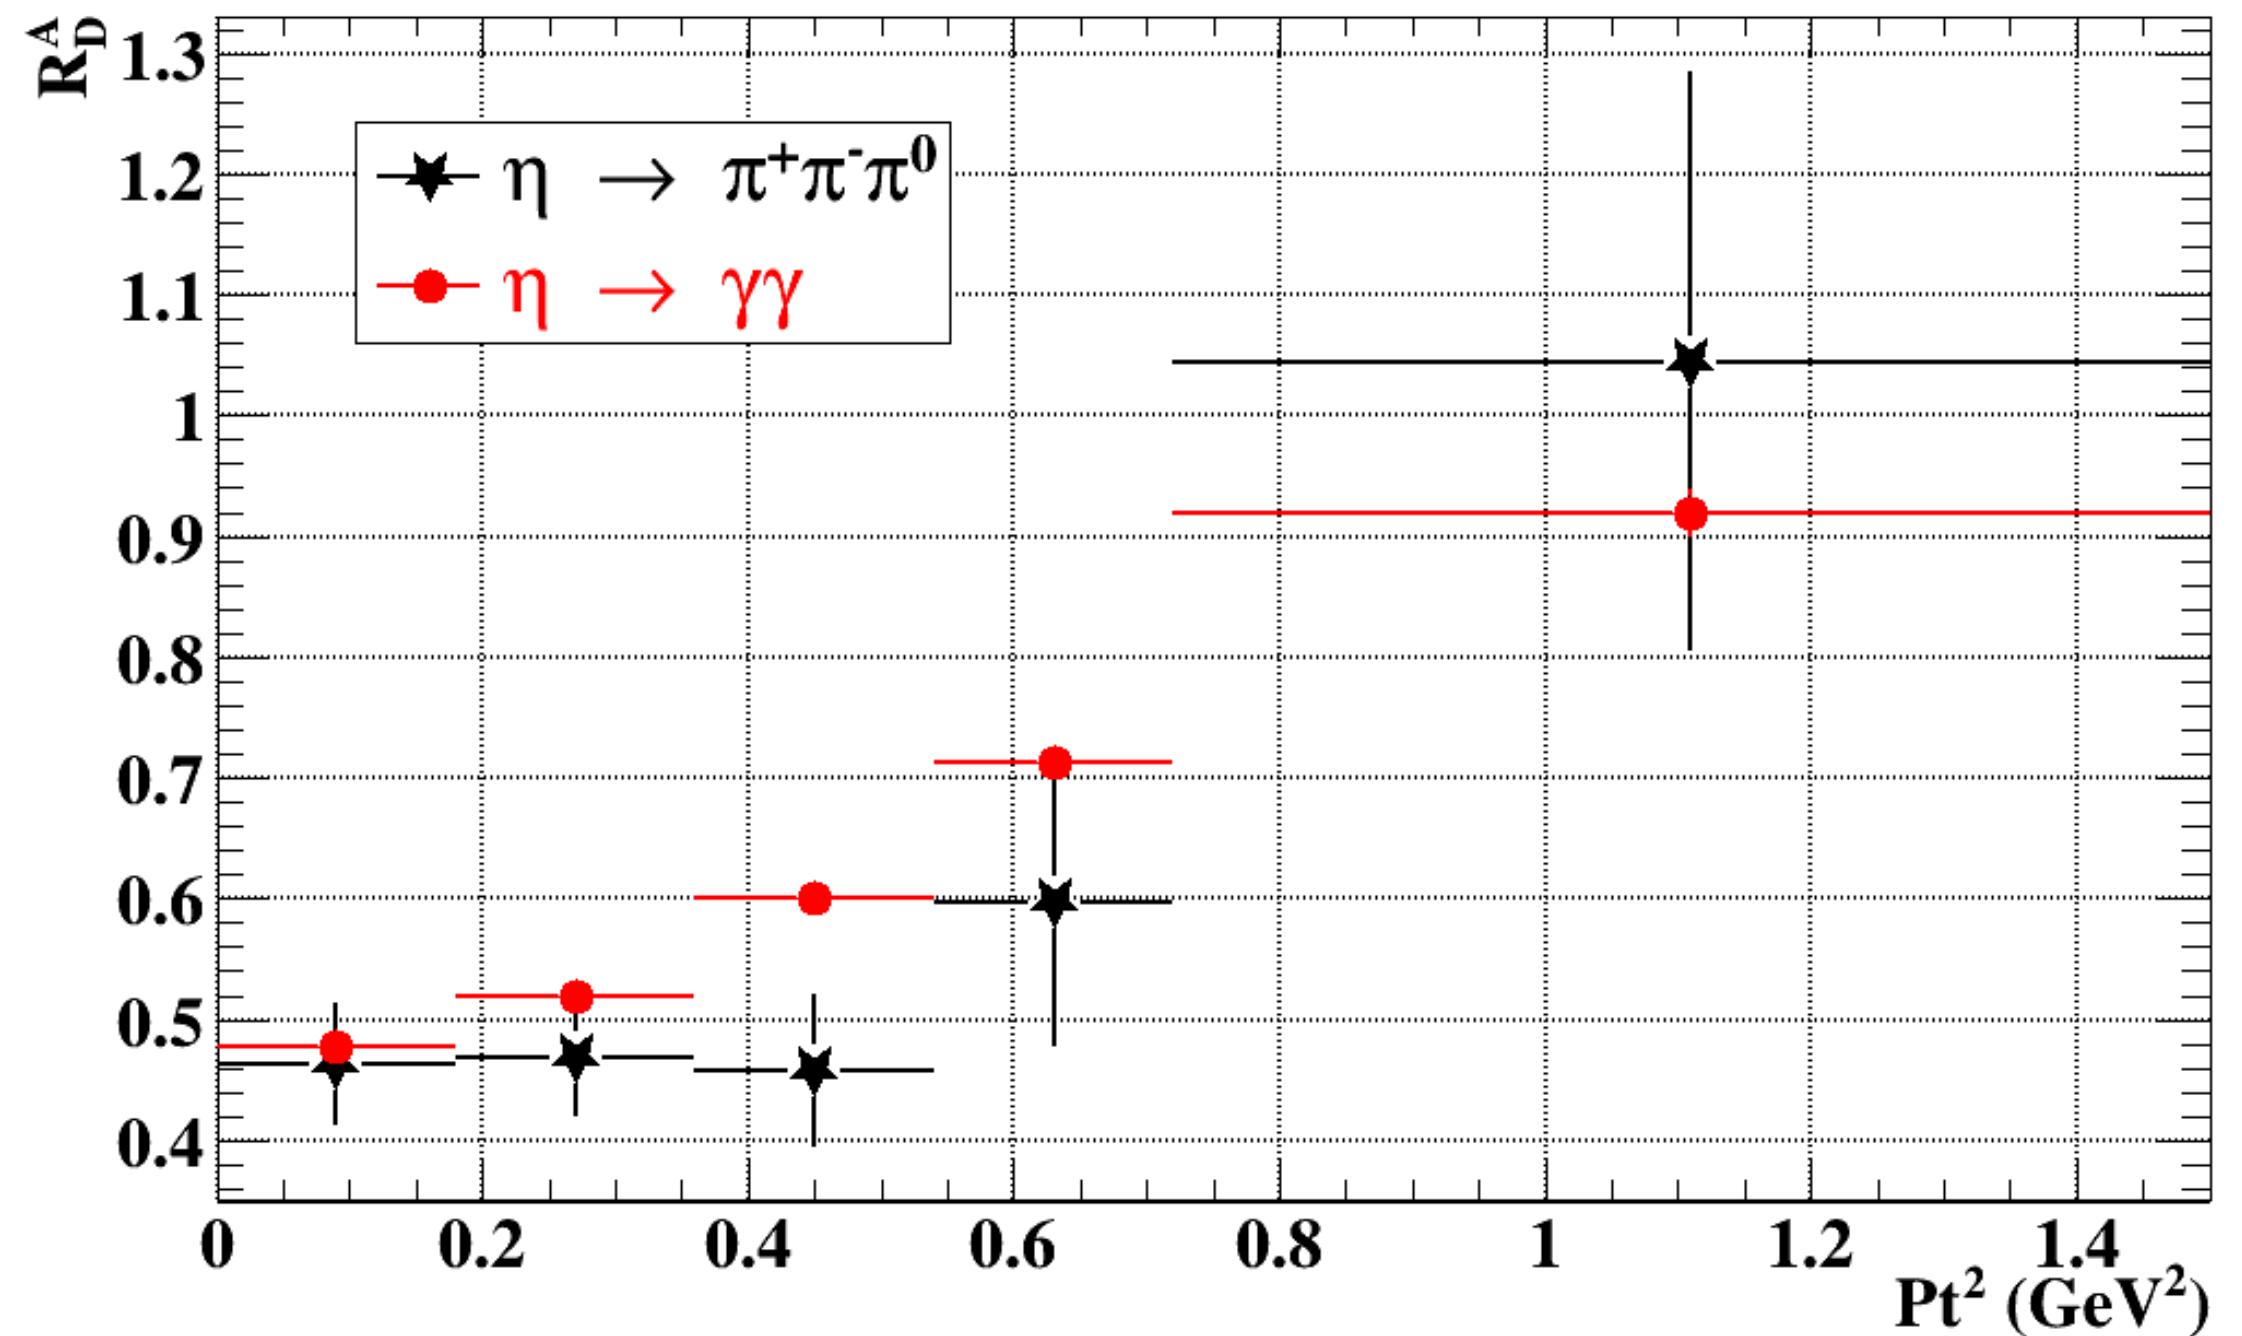

With background subtraction, there is a hint that the Cronin-like effect is seen for all three nuclei and both decay channels, with very large statistical uncertainties.

With background subtraction, there is a hint that the two channels give the same MR for three nuclei, within large statistical uncertainties.

Multiplicity Ratio, $\eta \rightarrow \pi^+\pi^-\pi^0 / \eta \rightarrow \gamma\gamma$ (BS)

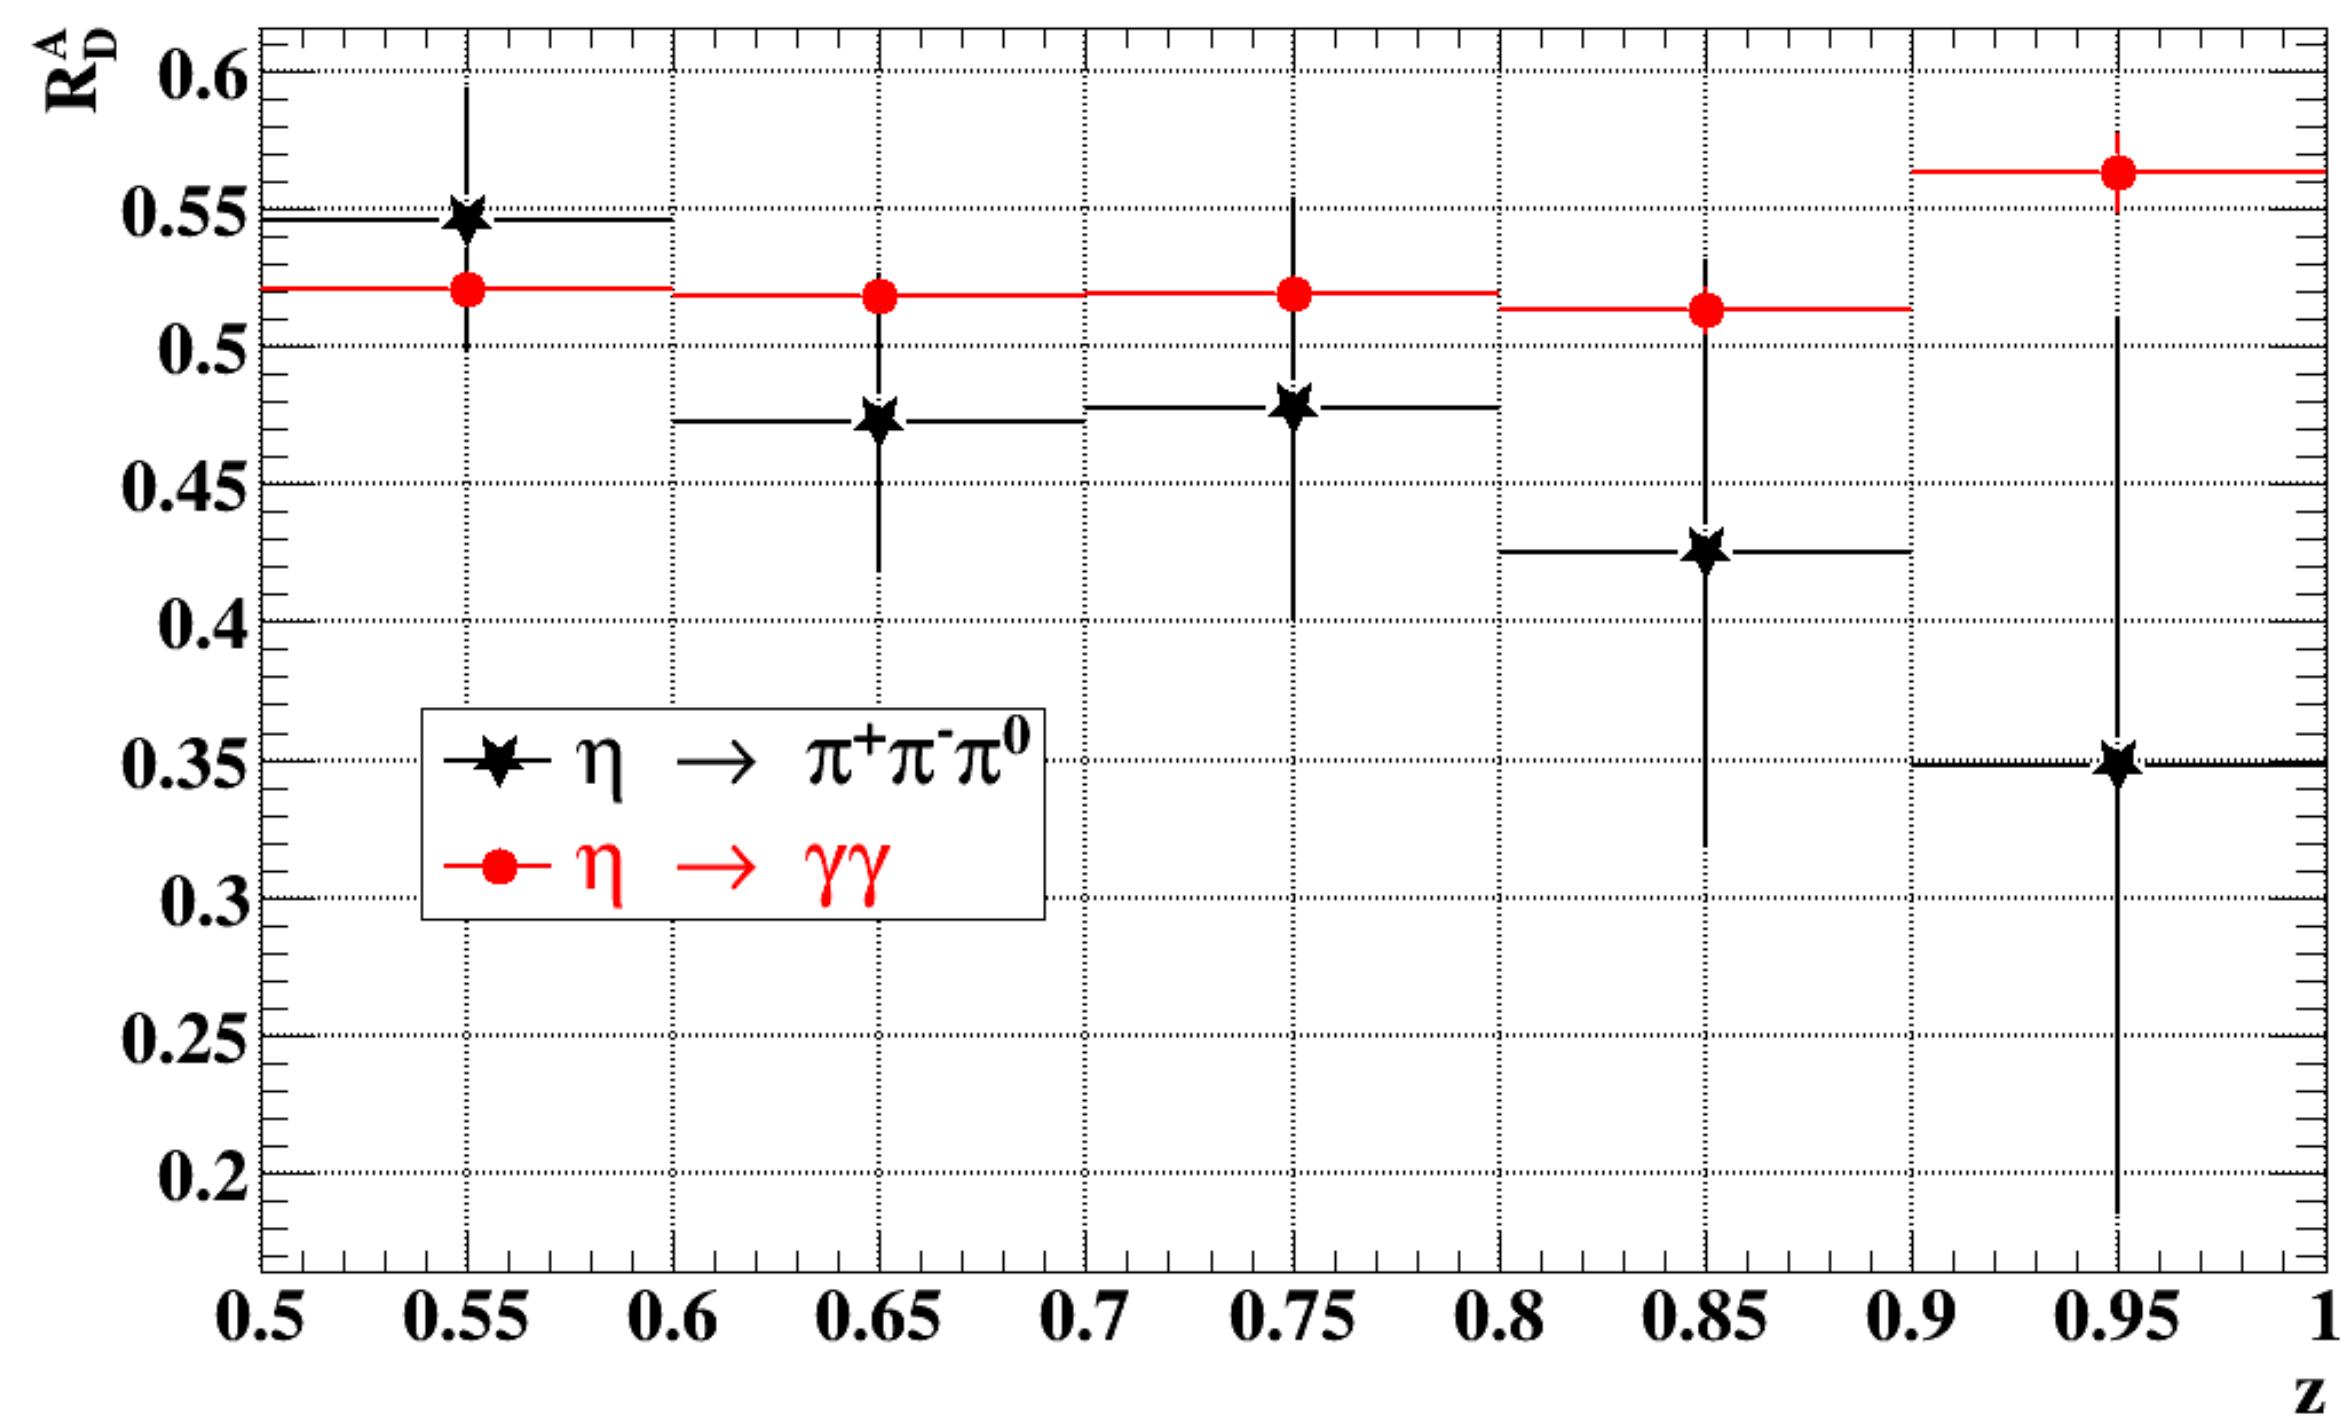

Multiplicity Ratio $\eta \rightarrow \gamma\gamma / \eta \rightarrow \pi^+\pi^-\pi^0$ on Iron

The expected attenuation at high z is not yet clearly seen on the iron nucleus

The expected Cronin-type enhancement is clearly seen in both channels for the iron nucleus where the statistical information is best

Multiplicity Ratio $\eta \rightarrow \gamma\gamma / \eta \rightarrow \pi^+\pi^-\pi^0$ on Iron

Charged Pion Multiplicity Ratios

Prof. Hayk Hakobyan (PhD 2008) UTFSM, Dr. Raphaël Dupré (PhD 2011) IPN Orsay
Sebastián Moran (MSc student UTFSM, Thesis advisor Prof. Hayk Hakobyan)

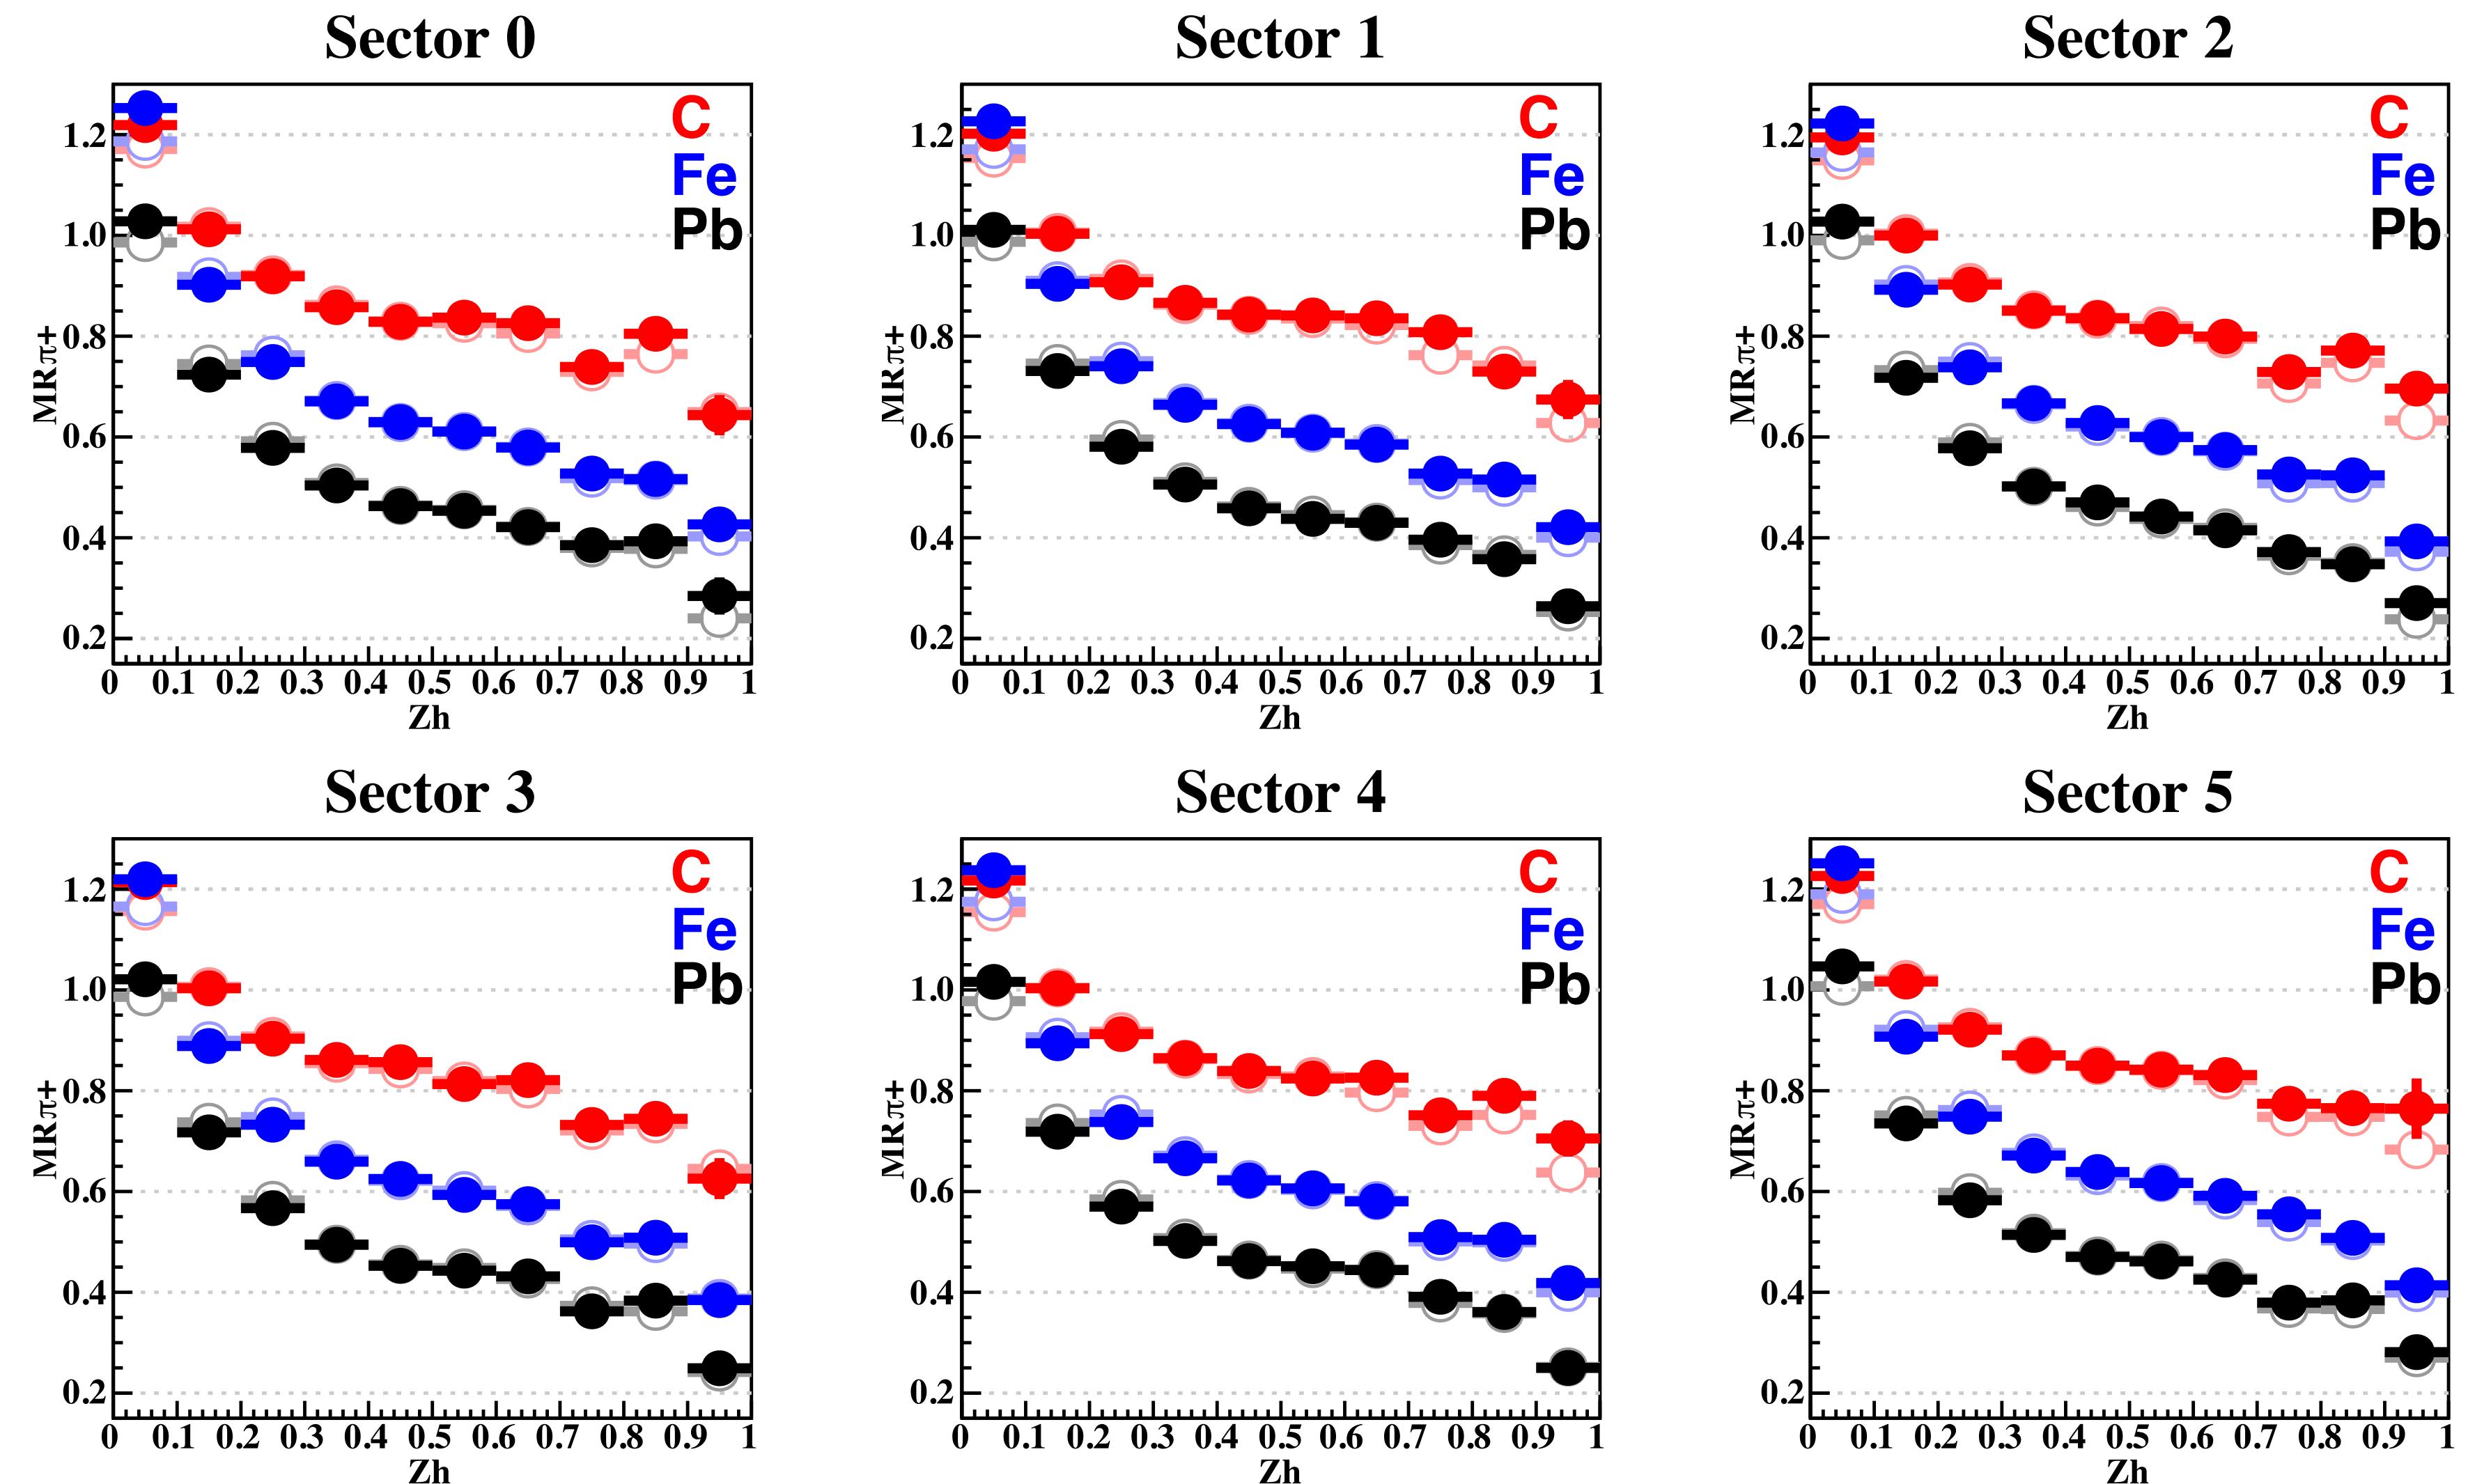

- Highest-statistics information for the positive pion - multidimensional studies possible up to **4-fold differential**. Negative pion has more complicated acceptance, but multidimensional studies still possible.
- Detailed comparison recently completed of two different analyses. All discrepancies are now resolved and the **analyses agree** at the 1% level.
- Analysis note written by Raphaël Dupré in 2016 (42 pages) may need to be slightly updated to reflect the new hybrid analysis; TBD. Previous plan was for a 3-pion 1D/2D paper to compare to HERMES.

https://www.jlab.org/Hall-B/shifts/admin/paper_reviews/2016/AnalysisNote_Dupre-5648485-2016-10-20-v1.pdf

π^+ 1D MR (can be up to 4D)

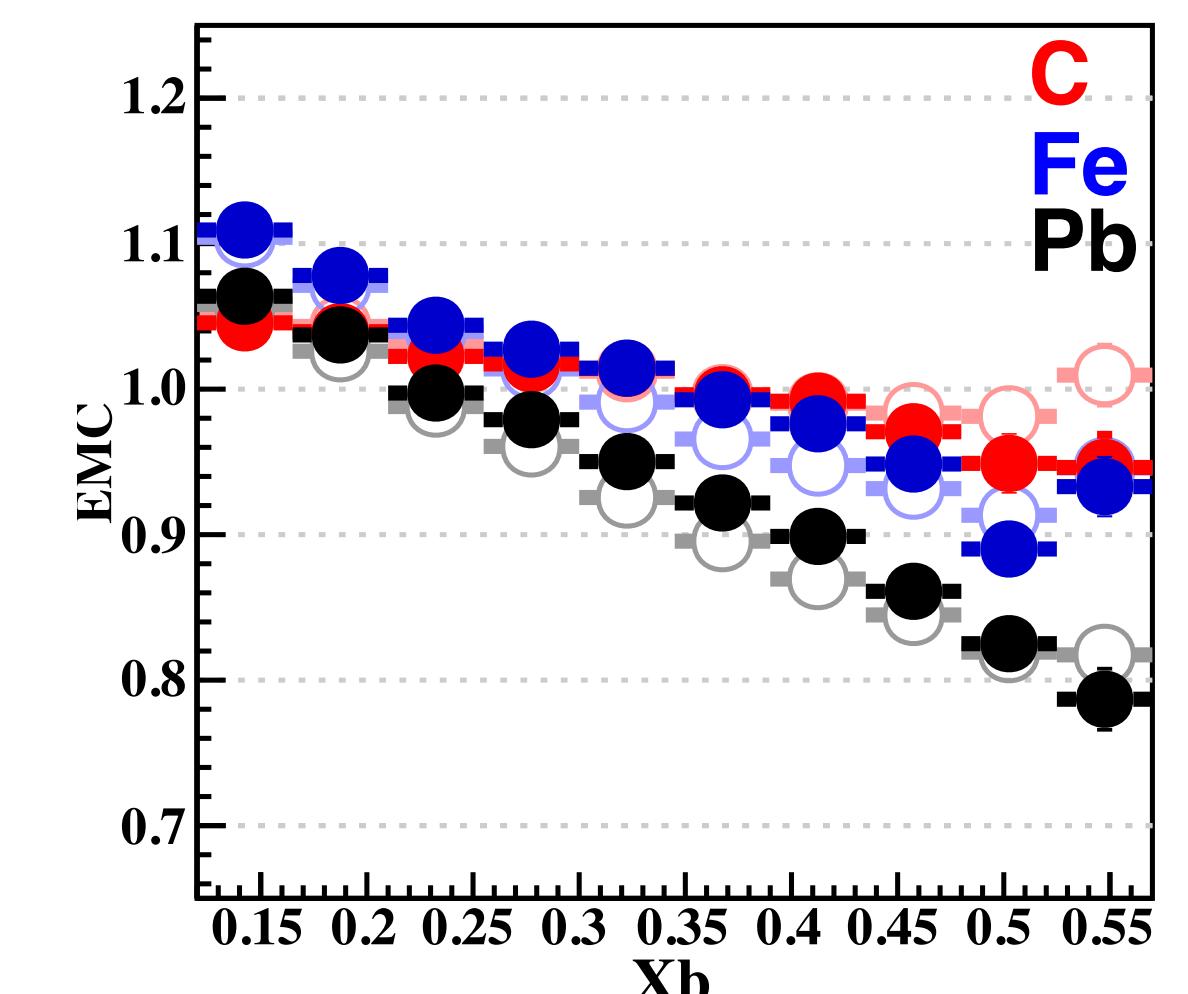

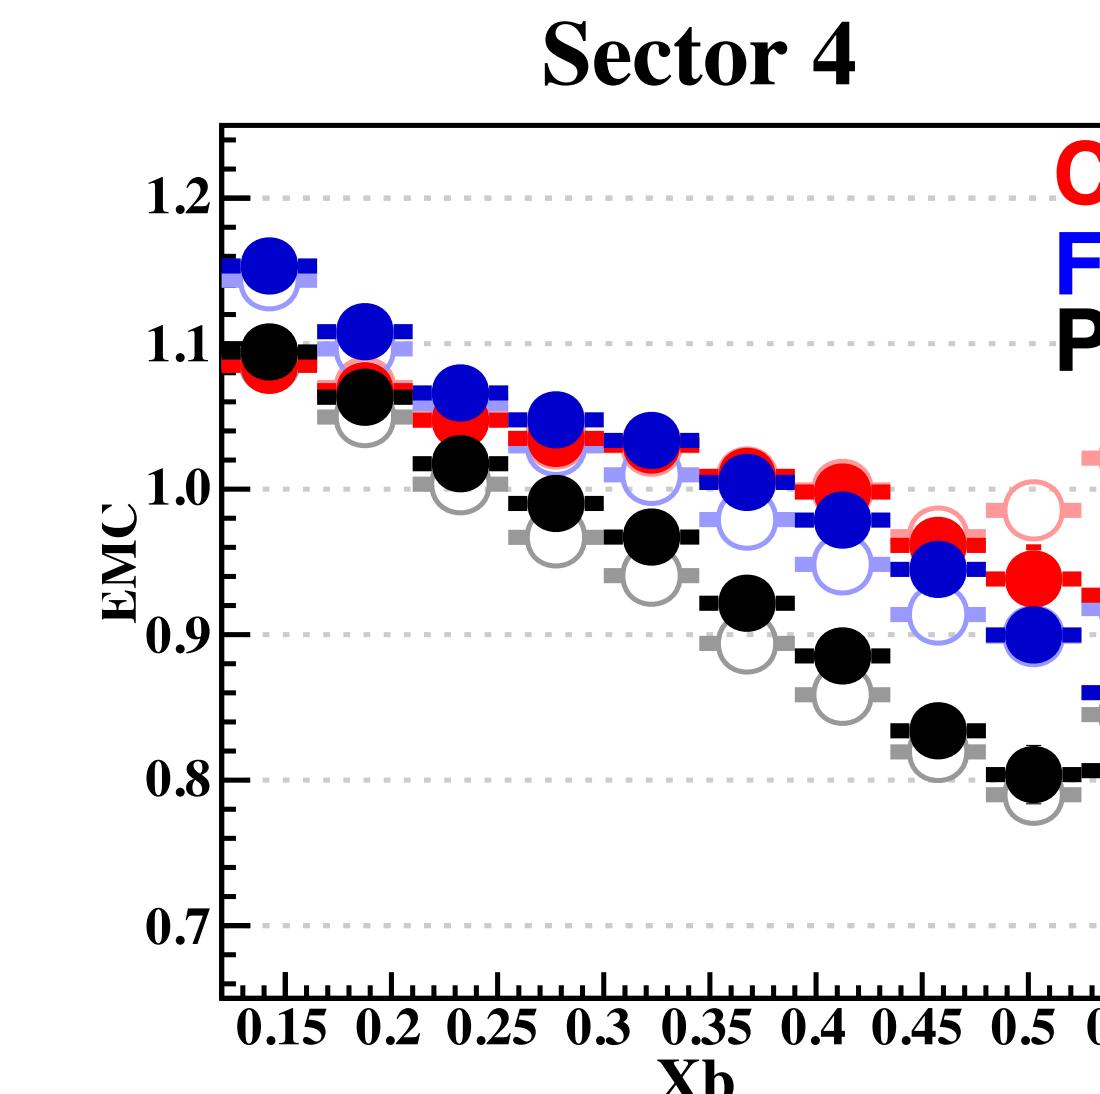

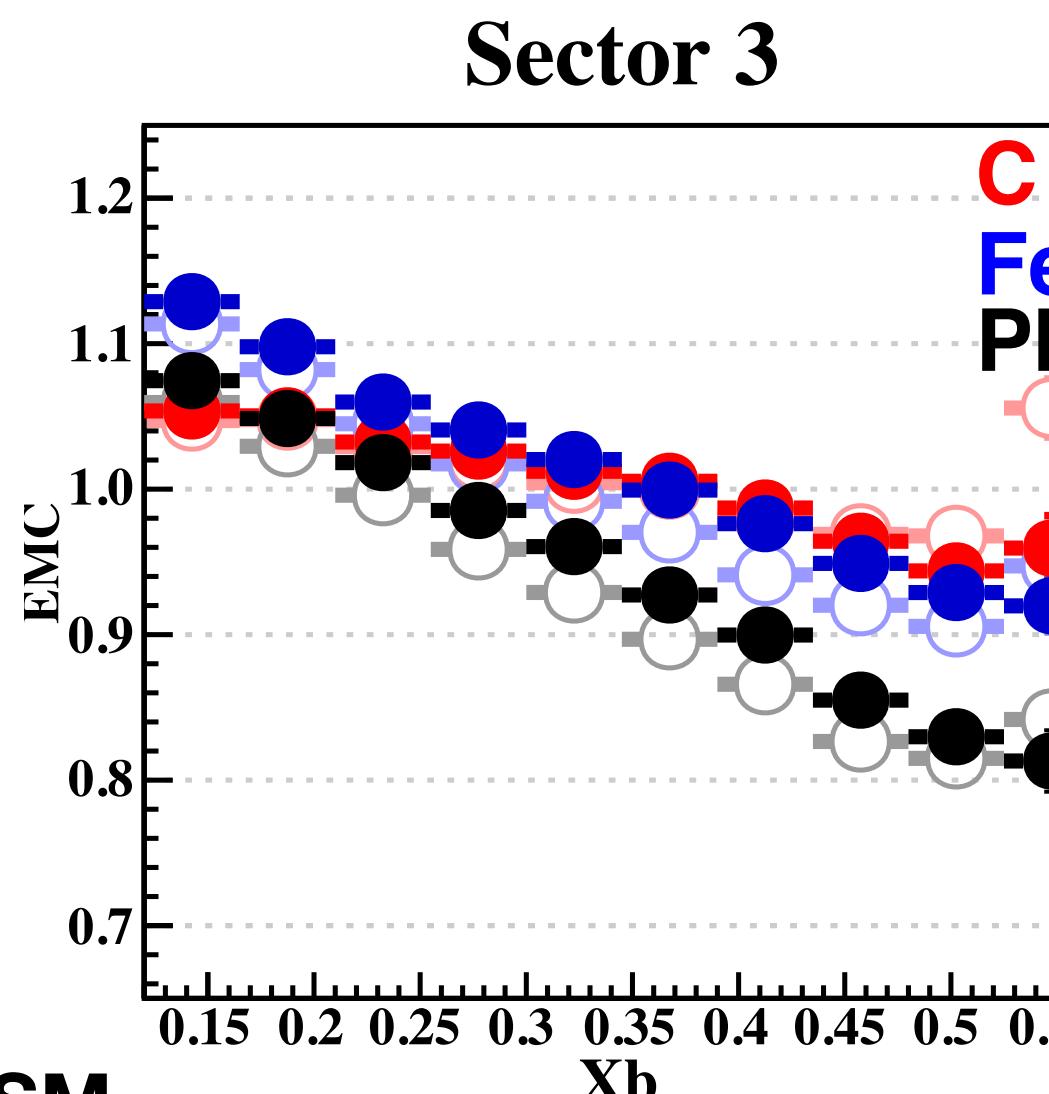

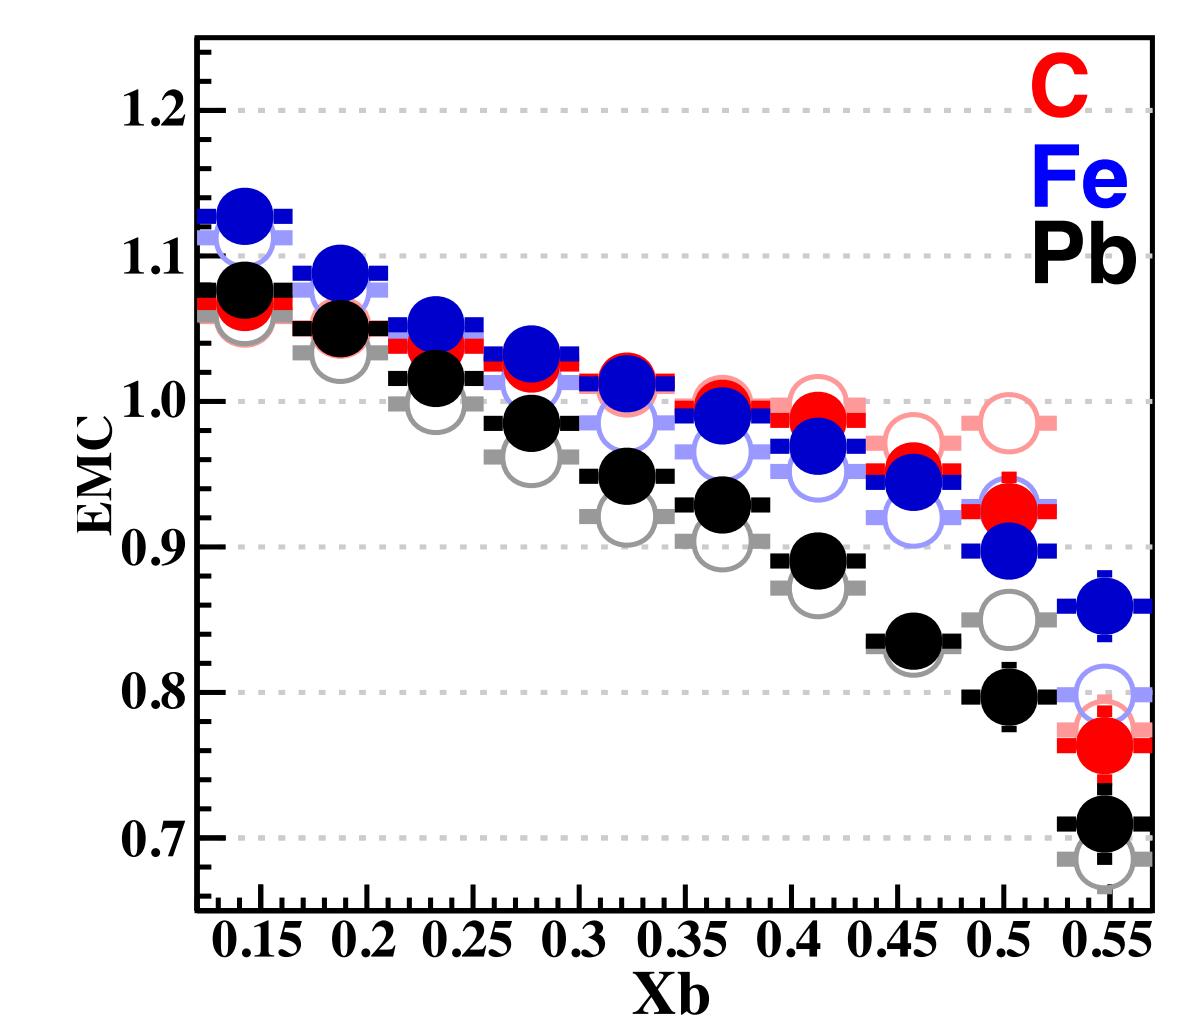

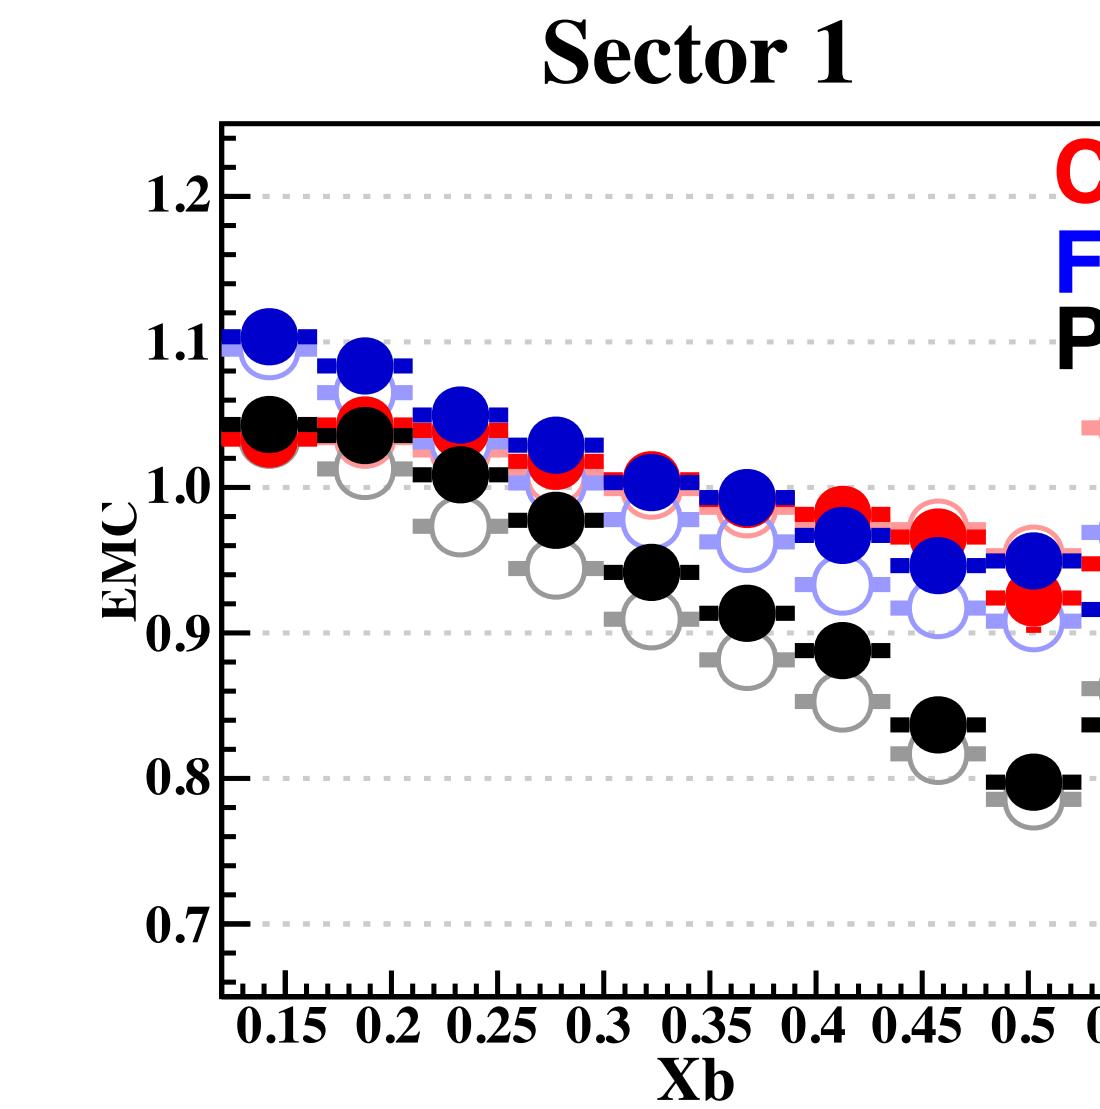

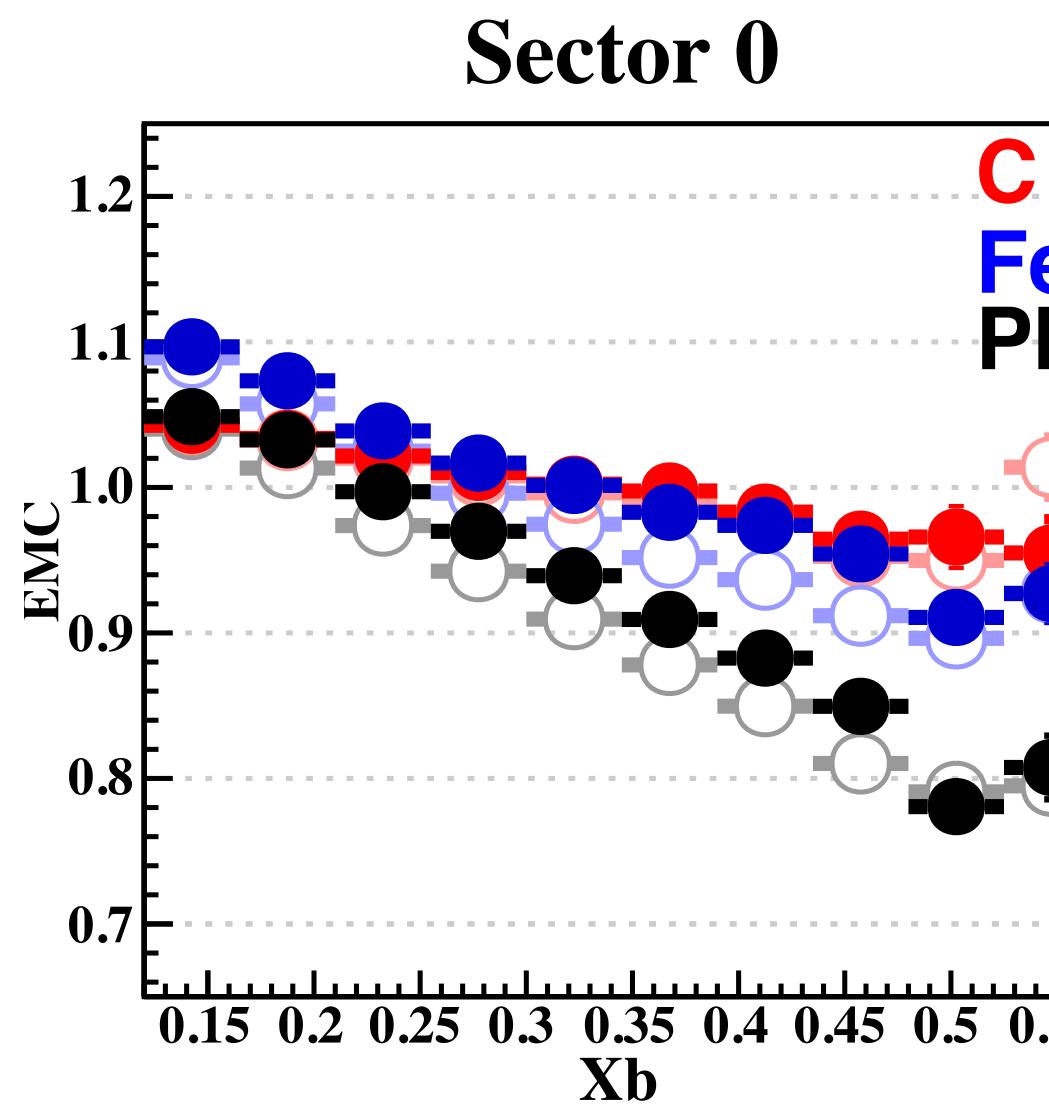

- MR with 5-fold differential acceptance correction, vs sector, SM analysis.

- Hollow symbols: no acceptance corrections

EMC Effect Plots (normalization for π^+ 1D MR)

- Hollow symbols: no acceptance corrections

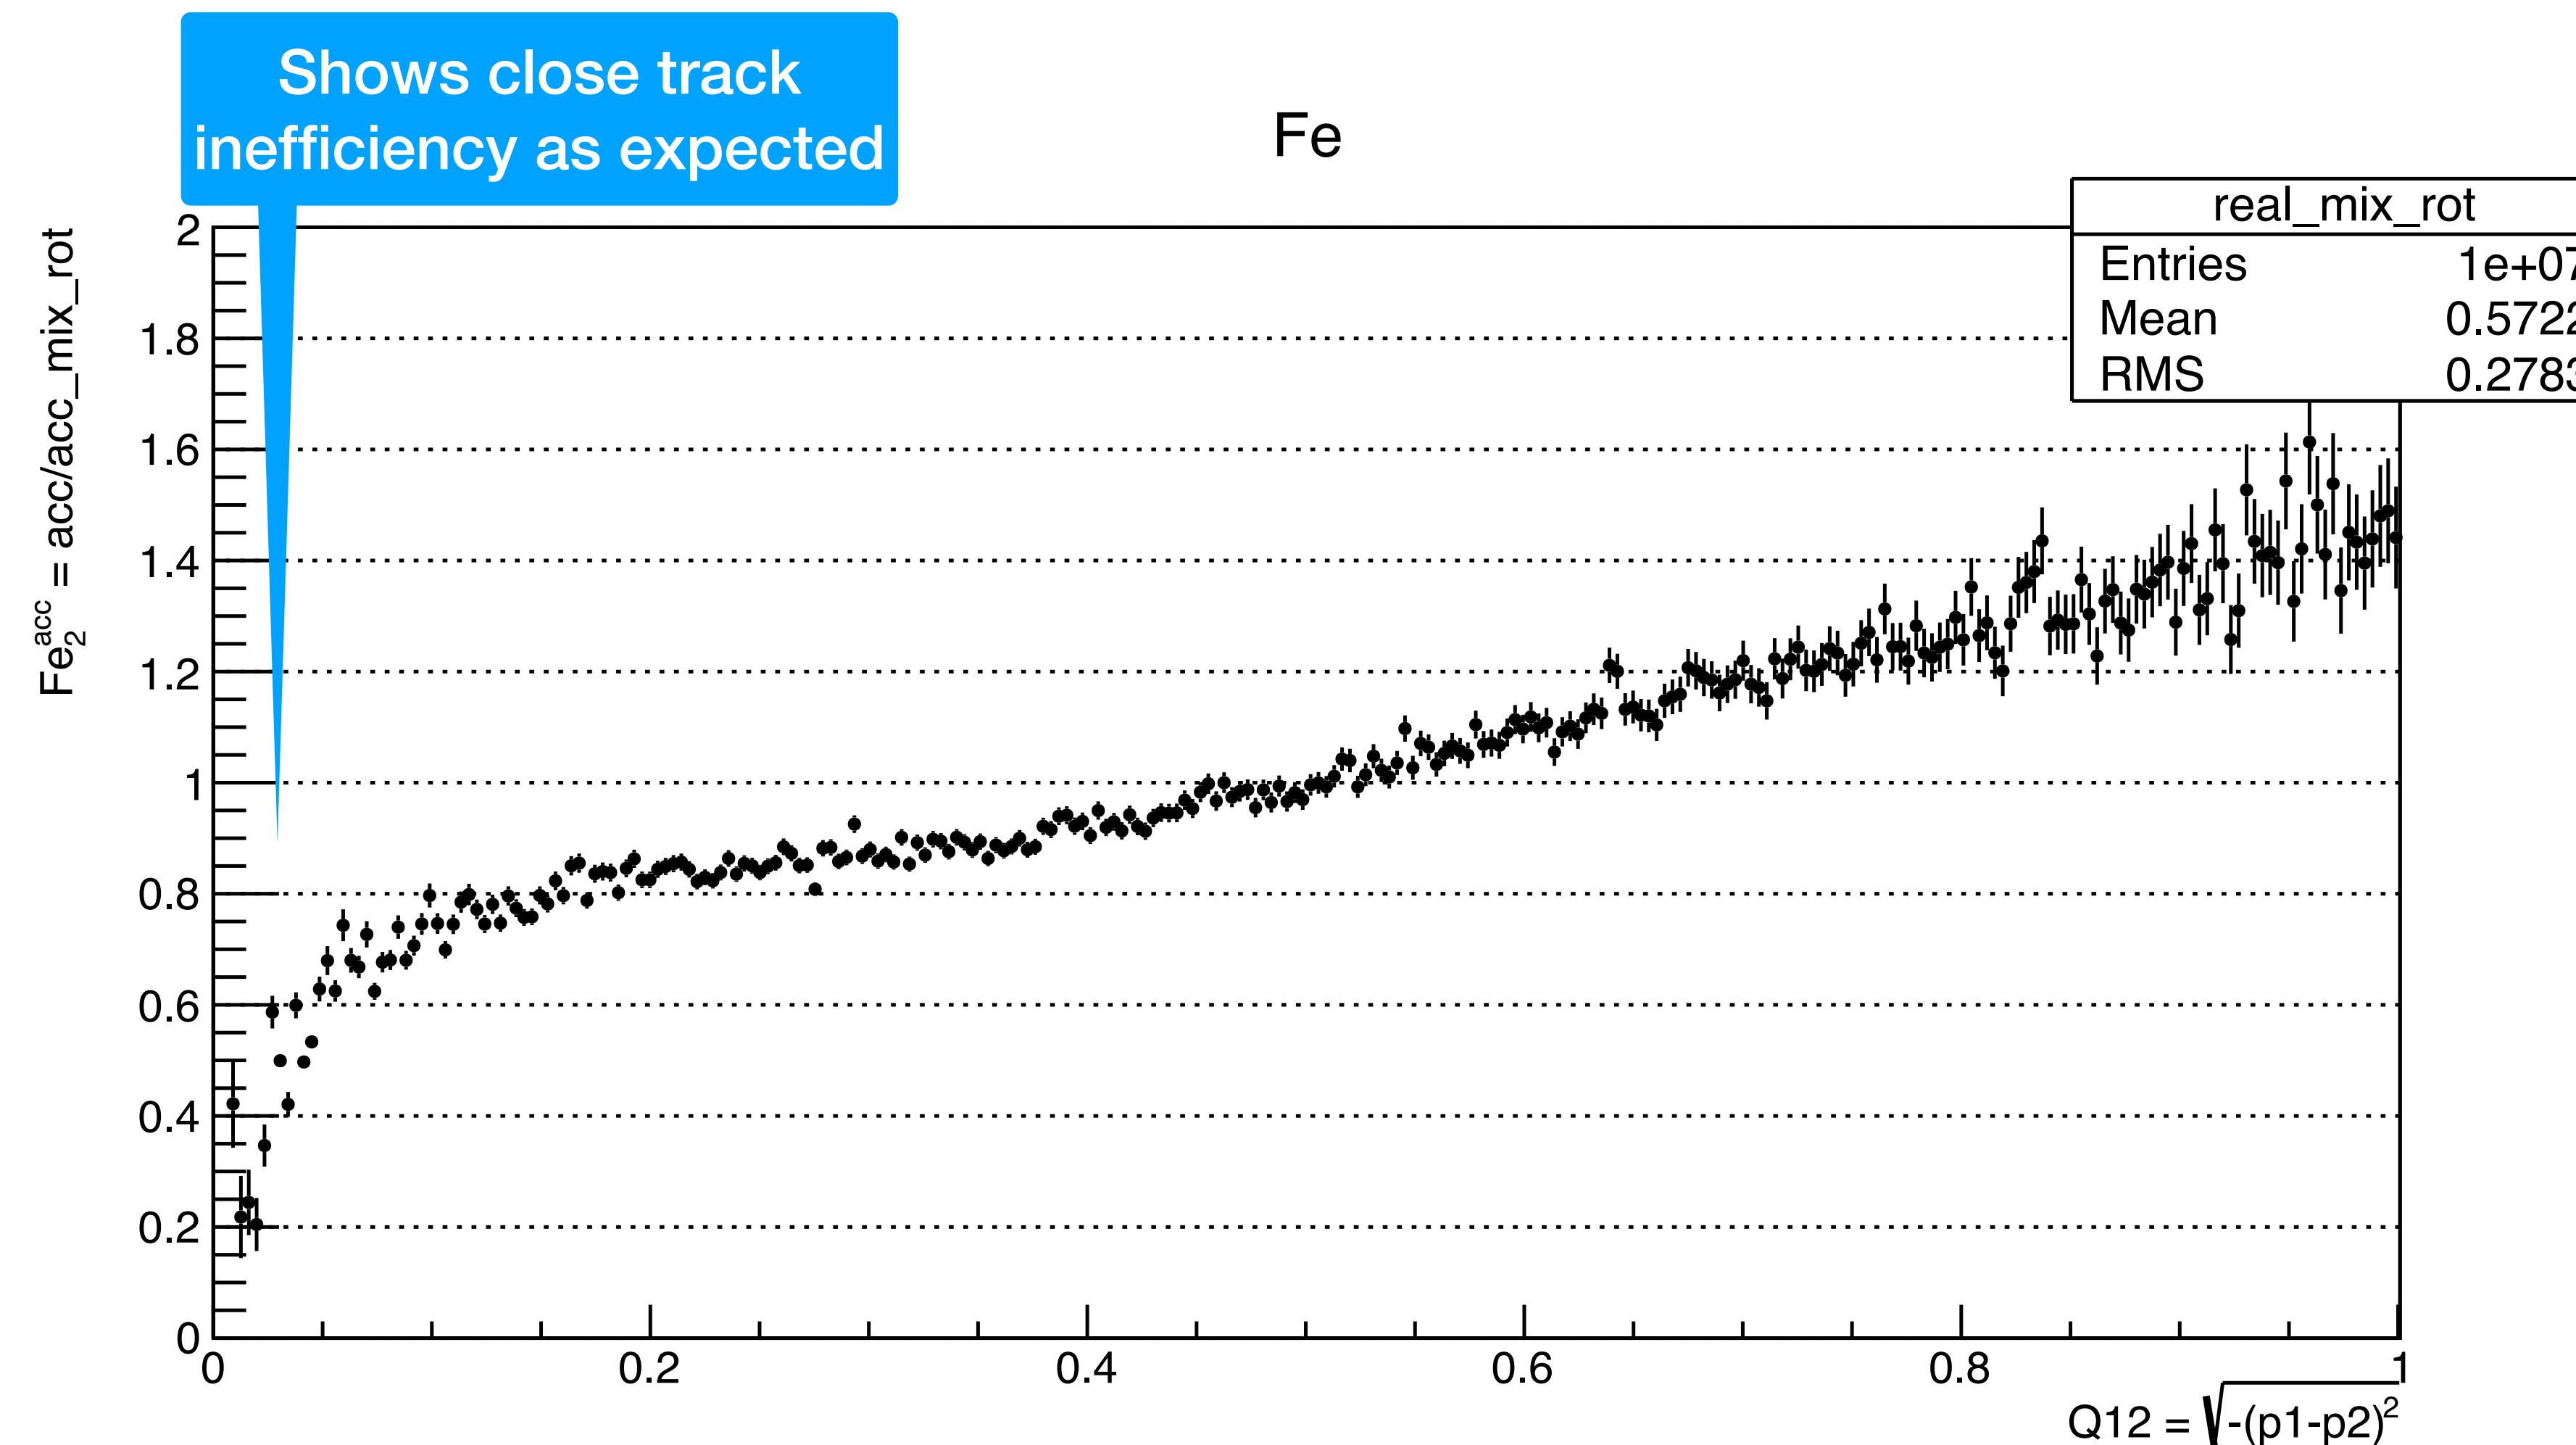

Di-hadron Studies with Nuclear Targets

- **Bose-Einstein Correlations** with DIS pions
 - Antonio Radic (MS student of Prof. Hayk Hakobyan, UTFSM)
- Di-pion **multiplicity ratio**
 - Dr. Ahmed El Alaoui, UTFSM
- Di-pion **azimuthal angular correlations**
 - Prof. Miguel Arratia, Postdoc Sebouh Paul, Sean Preins (PhD student) U. California Riverside; Luciano Arellano (MSc student of WB, UTFSM)
- Di-pion **p_T/q_T broadening**
 - Carolina Robles (PhD student of WB, UTFSM)

$\pi^+\pi^+$ Bose-Einstein Correlation Studies on Nuclei

Direct measurement of quark energy loss, and its connection to p_T broadening

Gabriela Hamilton and René Rios, UTFSM MSc students (thesis advisor WB)

$$-\Delta E_q = \frac{\alpha_s}{4} \Delta k_T^2 \cdot L$$

This is the classic equation relating quark energy loss and p_T broadening

We are trying to directly measure quark energy loss and then test this equation. It requires significant unfolding studies because the energy loss is quite small.

Conclusions

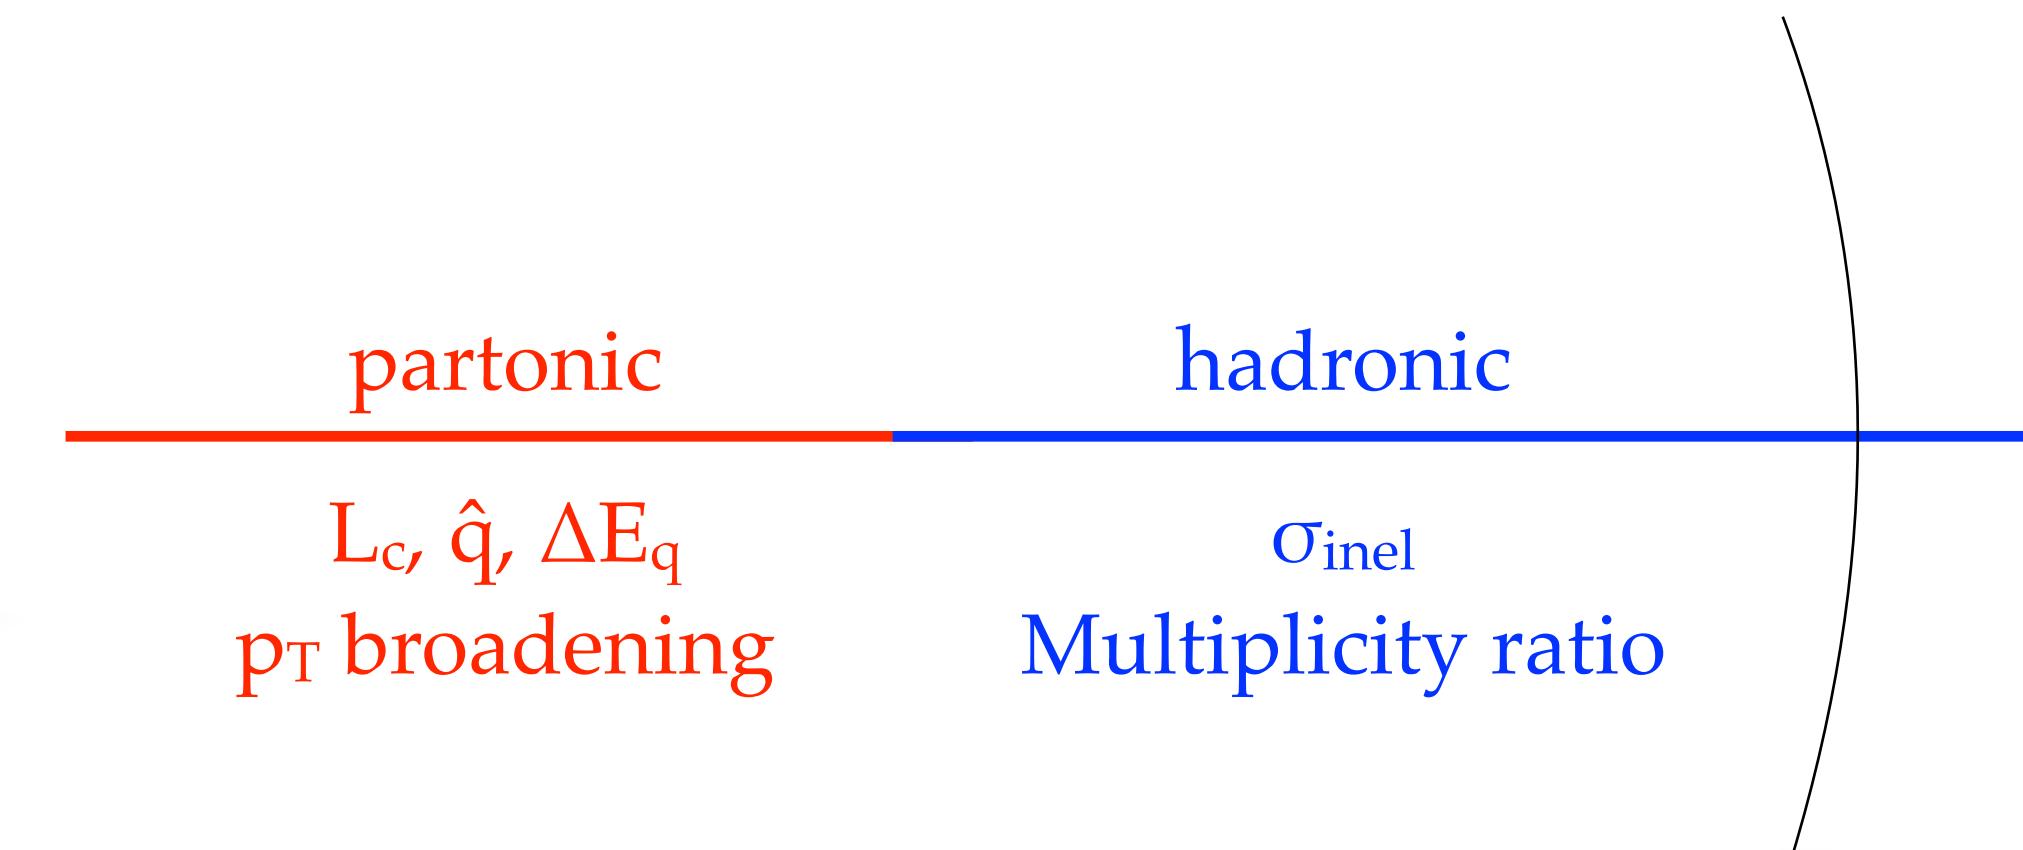

- Many interesting current results from EG2/CLAS6!
- Many more expected from CLAS12. A large and experienced team is waiting to get on the schedule.
- Clear extensions to EIC!

Backup Slides

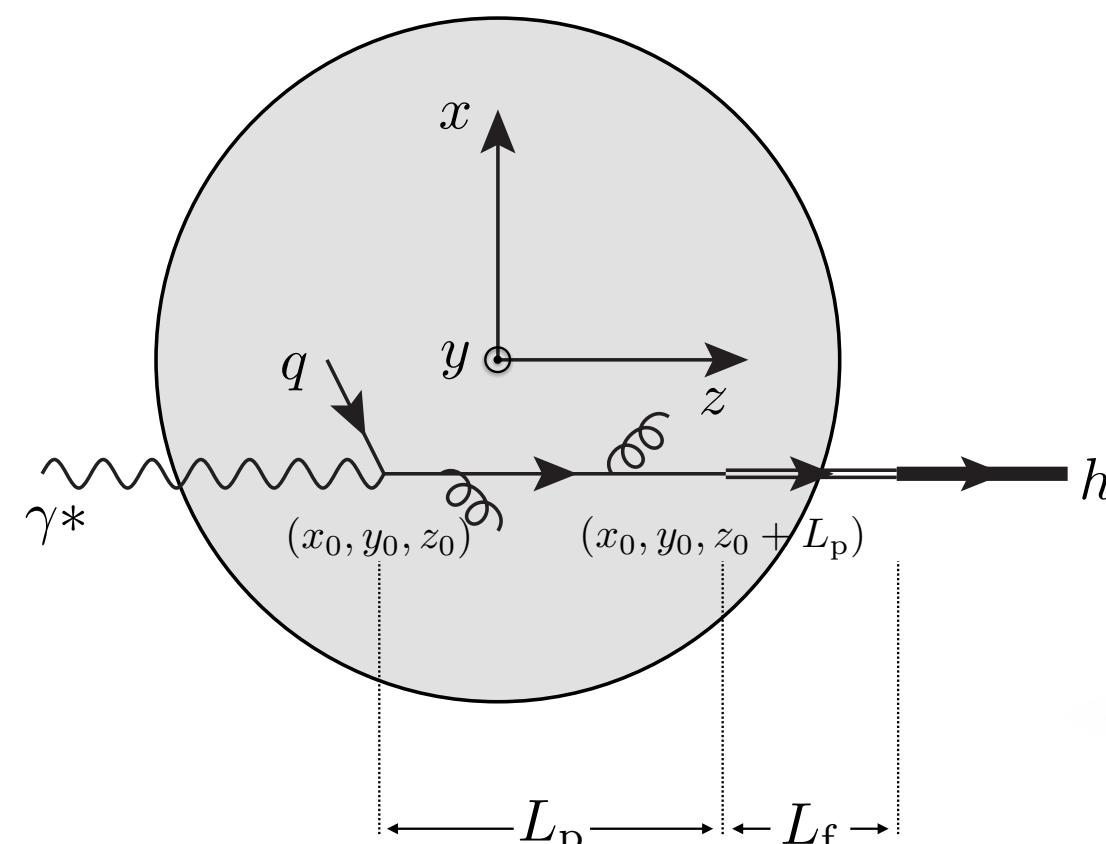

Definition of the BL model

Division into *partonic* and *hadronic* phases

Path of quark is divided
into “*partonic phase*”
and “*hadronic phase*”

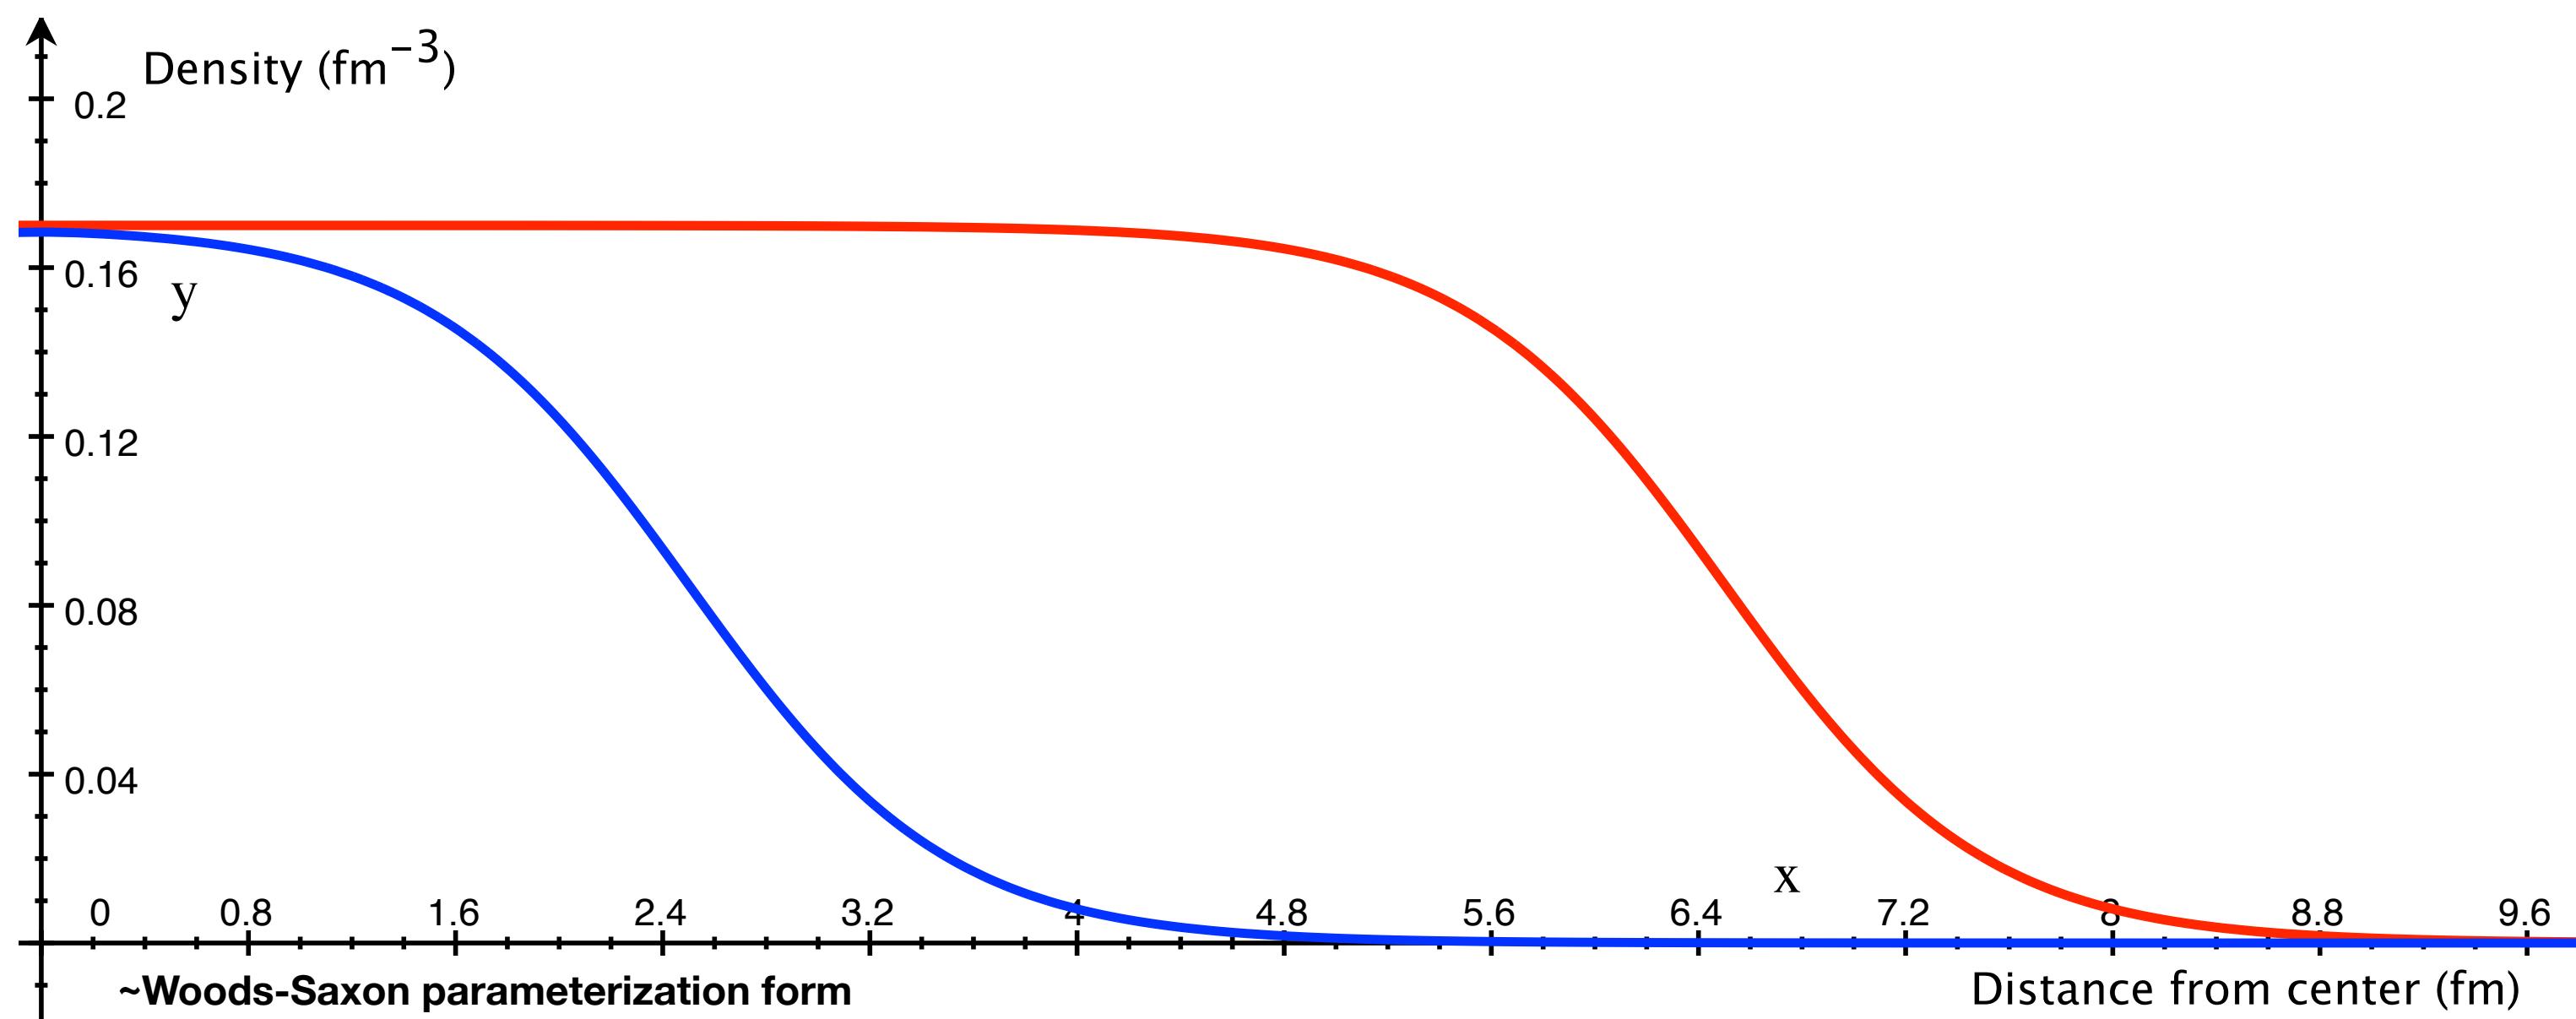

The *partonic phase* persists for a distance L_c , over which p_T broadening via \hat{q} , and *partonic energy loss* ΔE_q , occur

The *hadronic phase* follows the *partonic phase*, passing through the remainder of the medium, and causing attenuation of hadrons by an *inelastic interaction cross section* σ_{inel}

**Density distribution according to H. P. Blok and L. Lapikás,
PHYSICAL REVIEW C 73, 038201 (2006)**

Baseline Model Ingredients

p_T broadening is modeled as a line integral over a realistic density in the partonic phase, with 1 unique parameter, averaged over volume and color length L_c

$$\langle \Delta p_T^2 \rangle = \left\langle q_0 \int_{z=z_0}^{z=z_0+L_c^*} \rho(x_0, y_0, z) dz \right\rangle_{x_0, y_0, z_0, L_c}$$

unique parameter common parameter

Multiplicity ratio is modeled as a line integral over a realistic density in the hadronic phase, with 1 unique parameter, averaged over volume and color length L_c .

$$\langle R_M \rangle = \left\langle \exp(-\sigma \int_{z=z_0+L_c}^{z=z_{max}} \rho(x_0, y_0, z) dz) \right\rangle_{x_0, y_0, z_0, L_c}$$

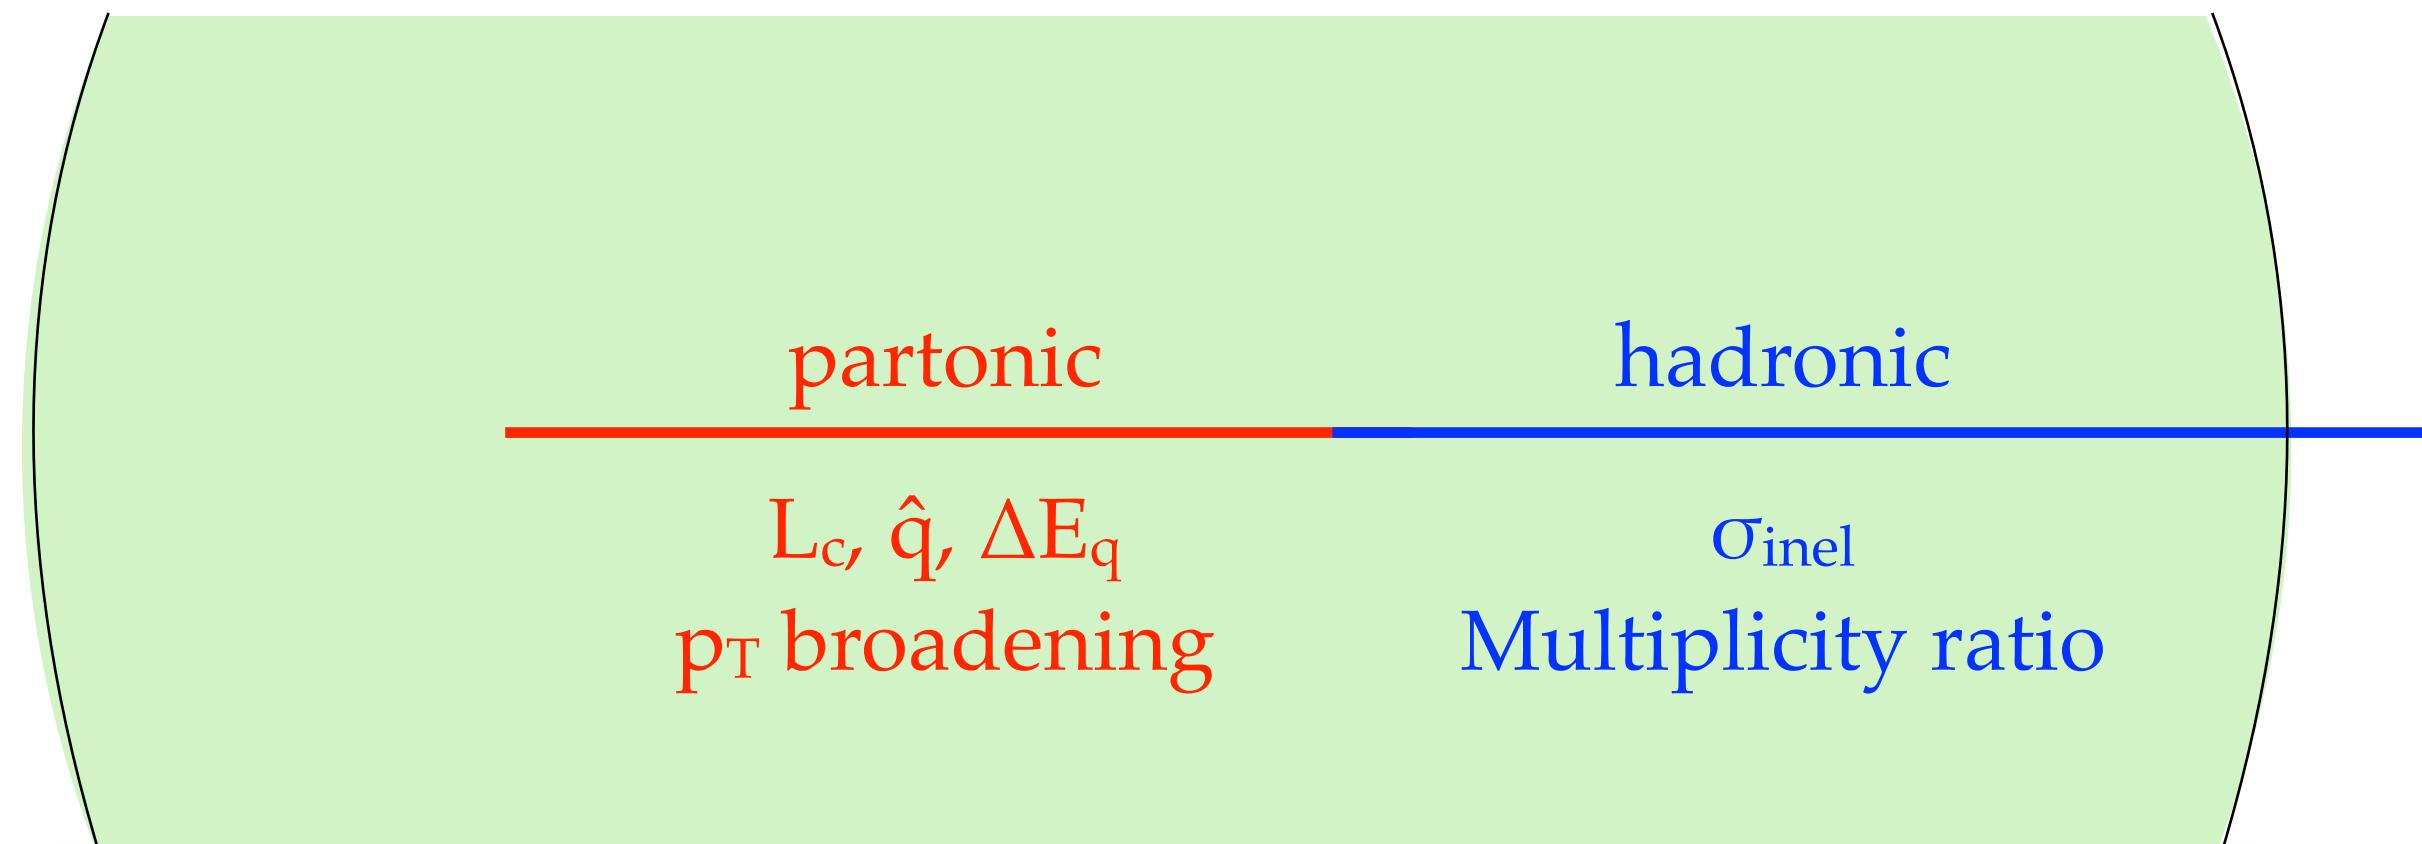

unique parameter common parameter

Total of 3 parameters in the baseline model. We often fix sigma at 30 or 40 mbarn.

The “common” parameter L_c couples the two observables together.

The coupling of the observables through L_c is the feature of this model that gives it much more discriminating power than the single-observable models used previously.

For example, for fixed q_0 and fixed σ , if L_c is *longer* (*longer partonic phase*) it simultaneously *increases* p_T broadening and *decreases* the multiplicity ratio. The amount of increase and decrease depends on the size of the nucleus and on the size of L_c . Thus the description is highly constrained.

Model Assumptions

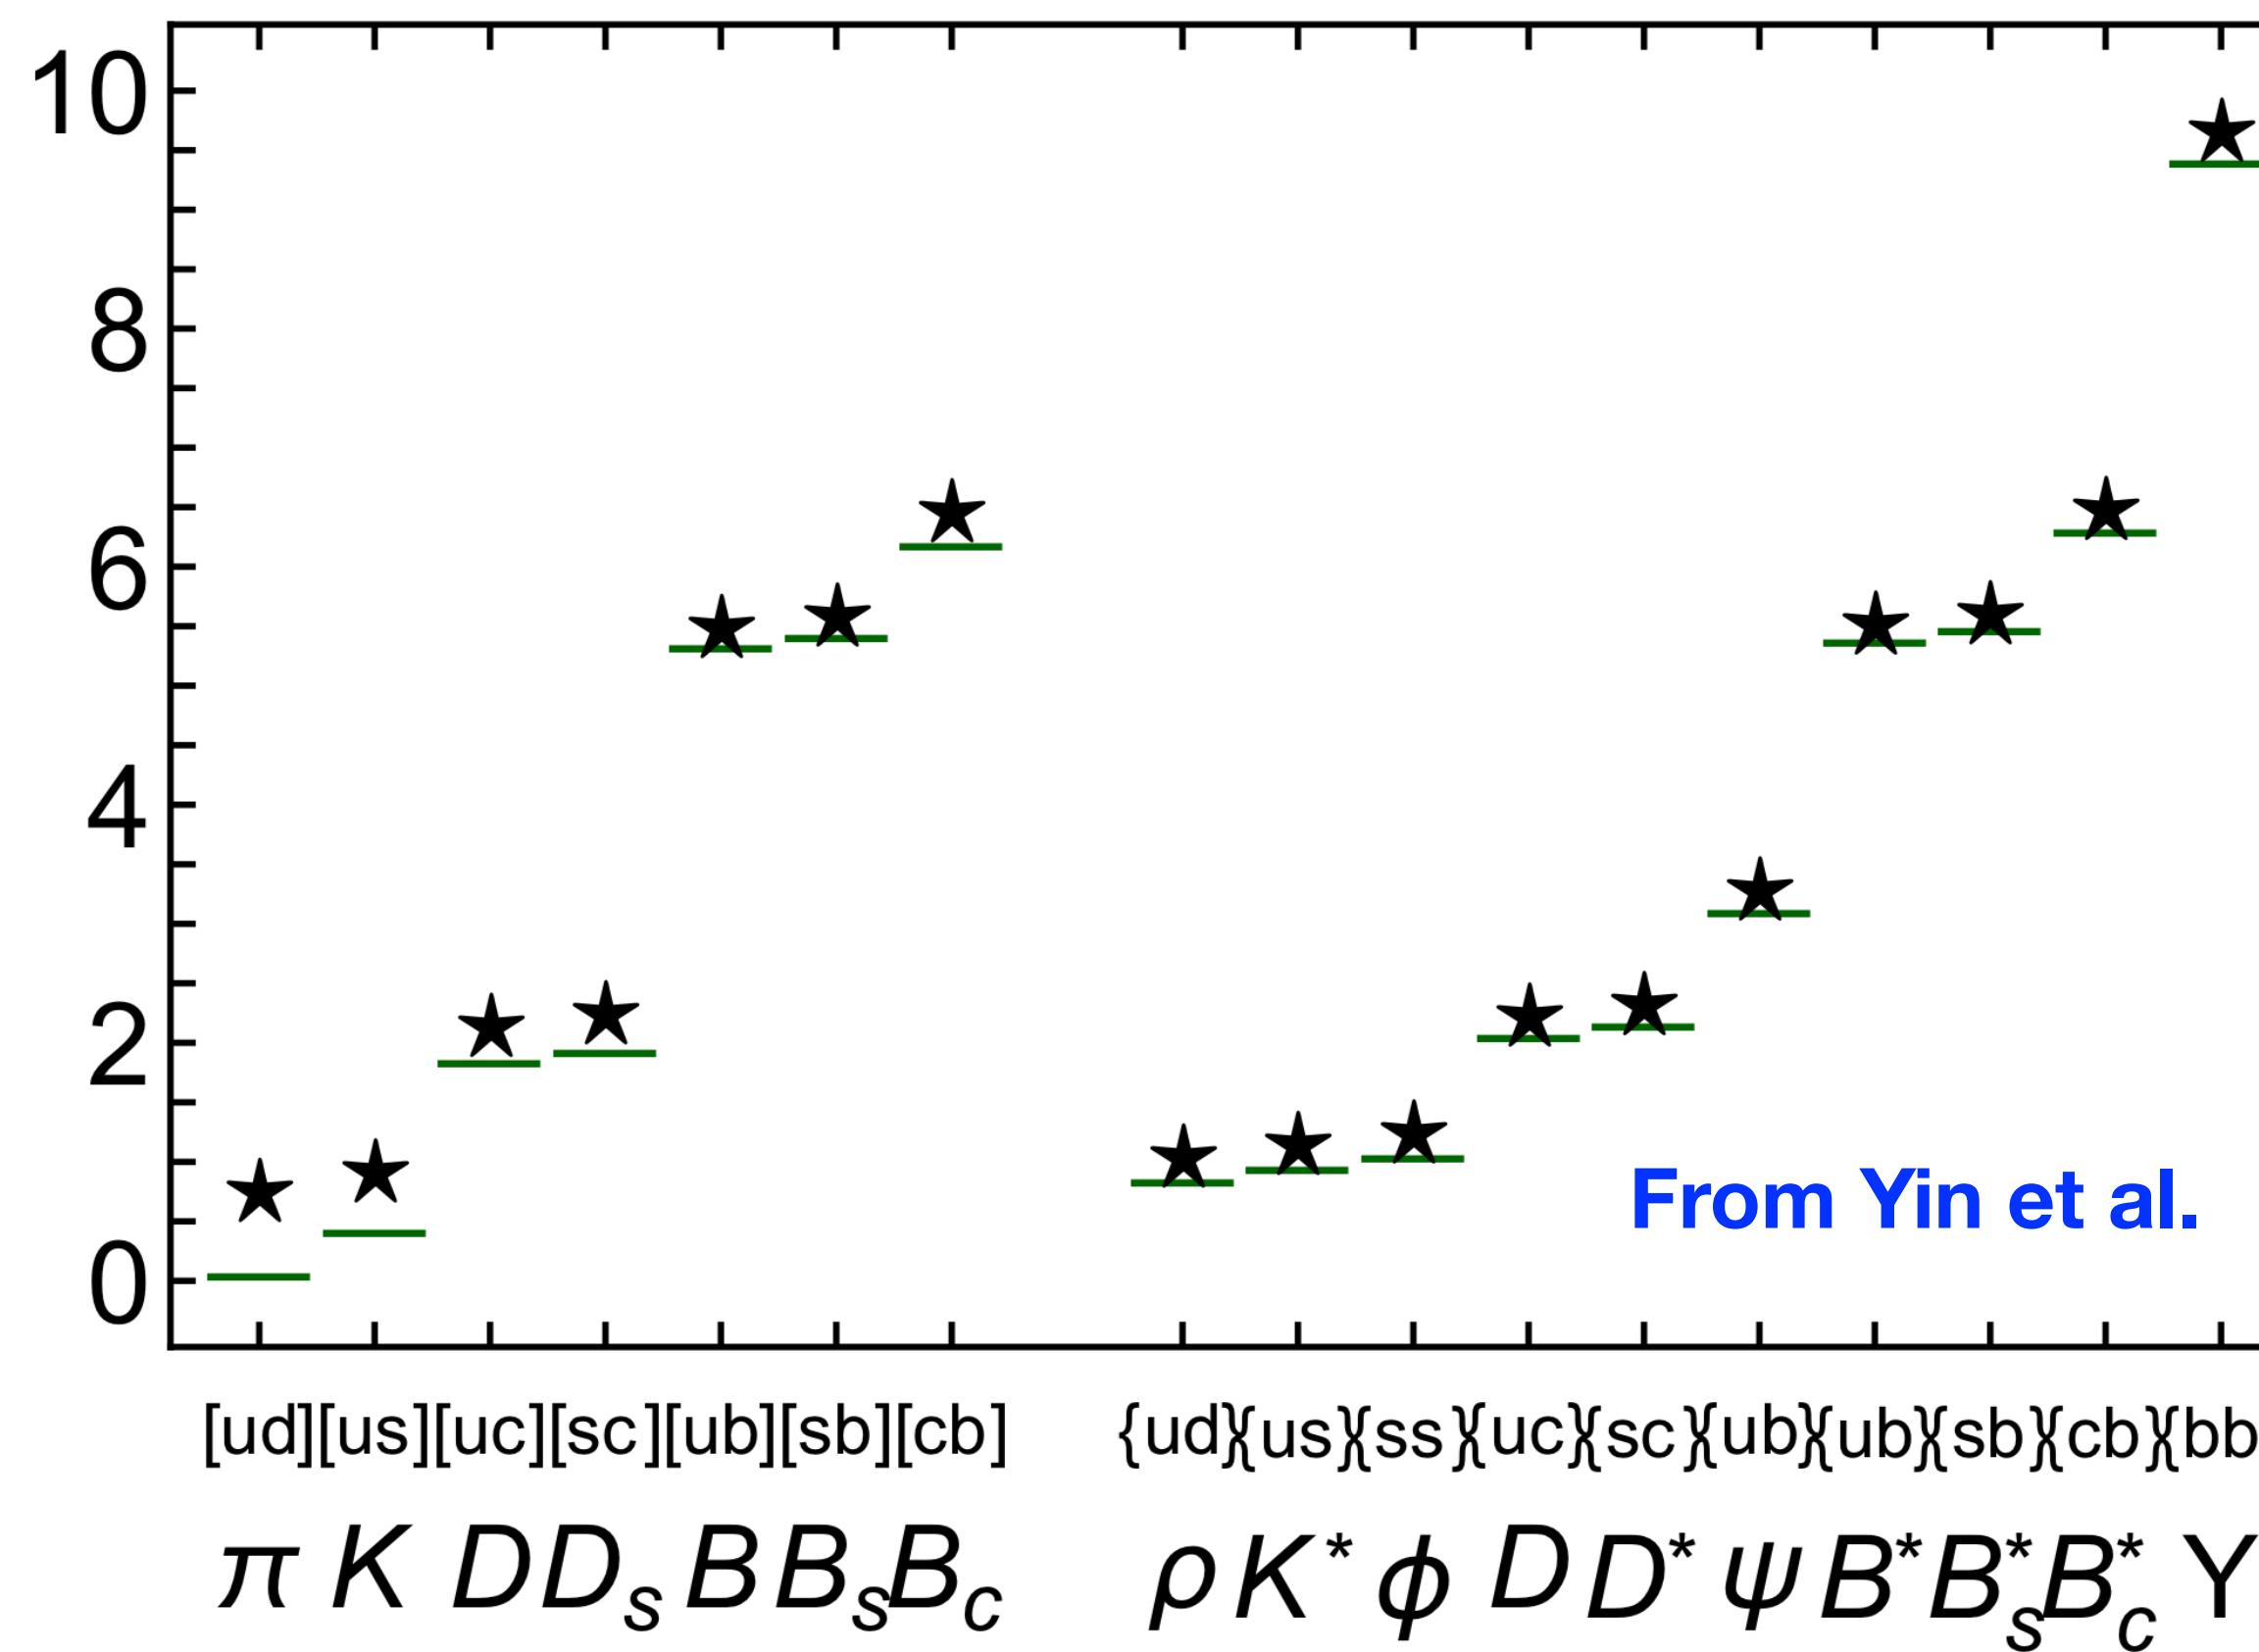

- Only **two dynamical processes** are involved - quark energy loss and (pre-)hadron inelastic interactions
- **Straight-line propagation** of the struck quark (soft-gluon assumption)
- **Two stages** of propagation: first, as a color octet system, and second as a color singlet system.
- Non-zero hadron **formation time** (reduced inelastic cross section).
- **Fluctuations** affecting the yield are **neglected** (only average values). Decreasing exponential form for pre-hadron cross section.
- Functional **form** of the color lifetime: either exponential or constant.

The Diquark Argument

Masses of ground-state mesons and baryons, including those with heavy quarks

Pei-Lin Yin,^{1,*} Chen Chen,^{2,†} Gastão Krein,² Craig D. Roberts,^{3,‡} Jorge Segovia,⁴ and Shu-Sheng Xu¹

arXiv 1903.00160

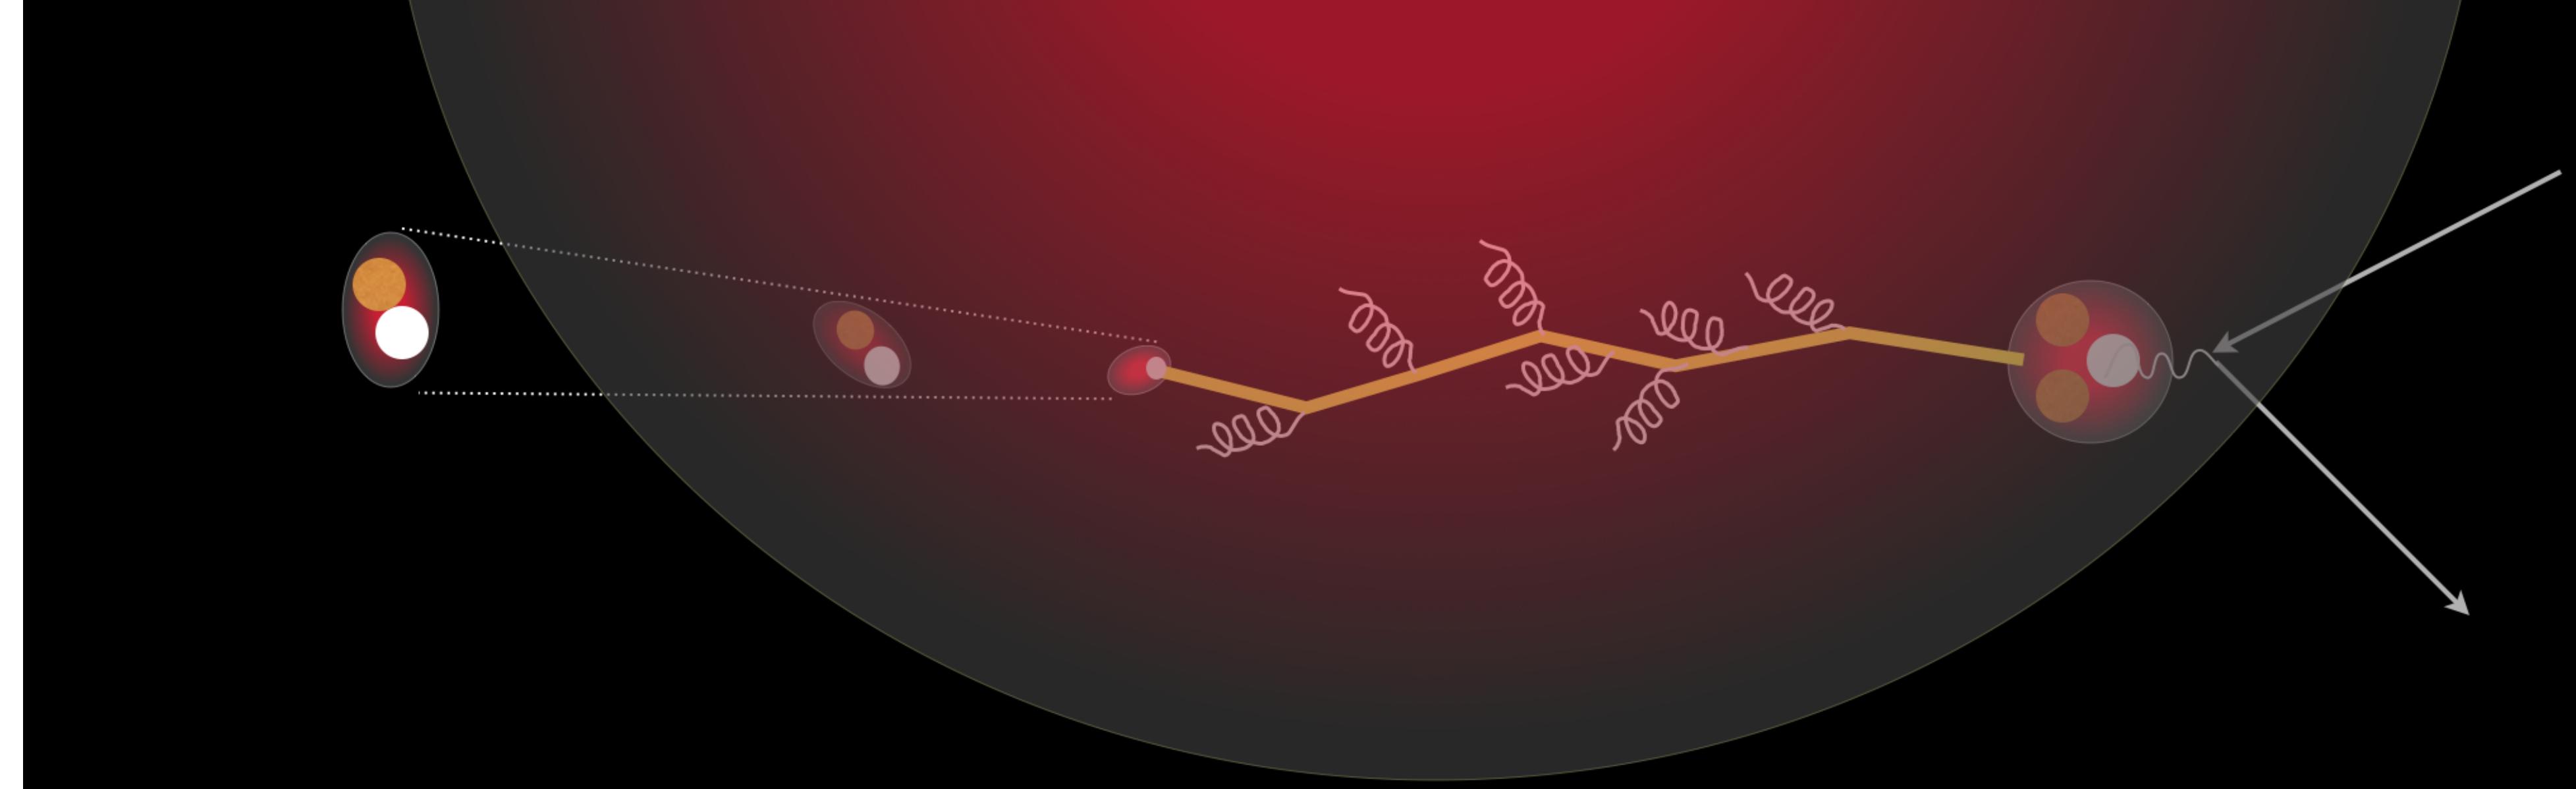

The **ud diquarks are heavy. This is very relevant to what follows in this talk.**

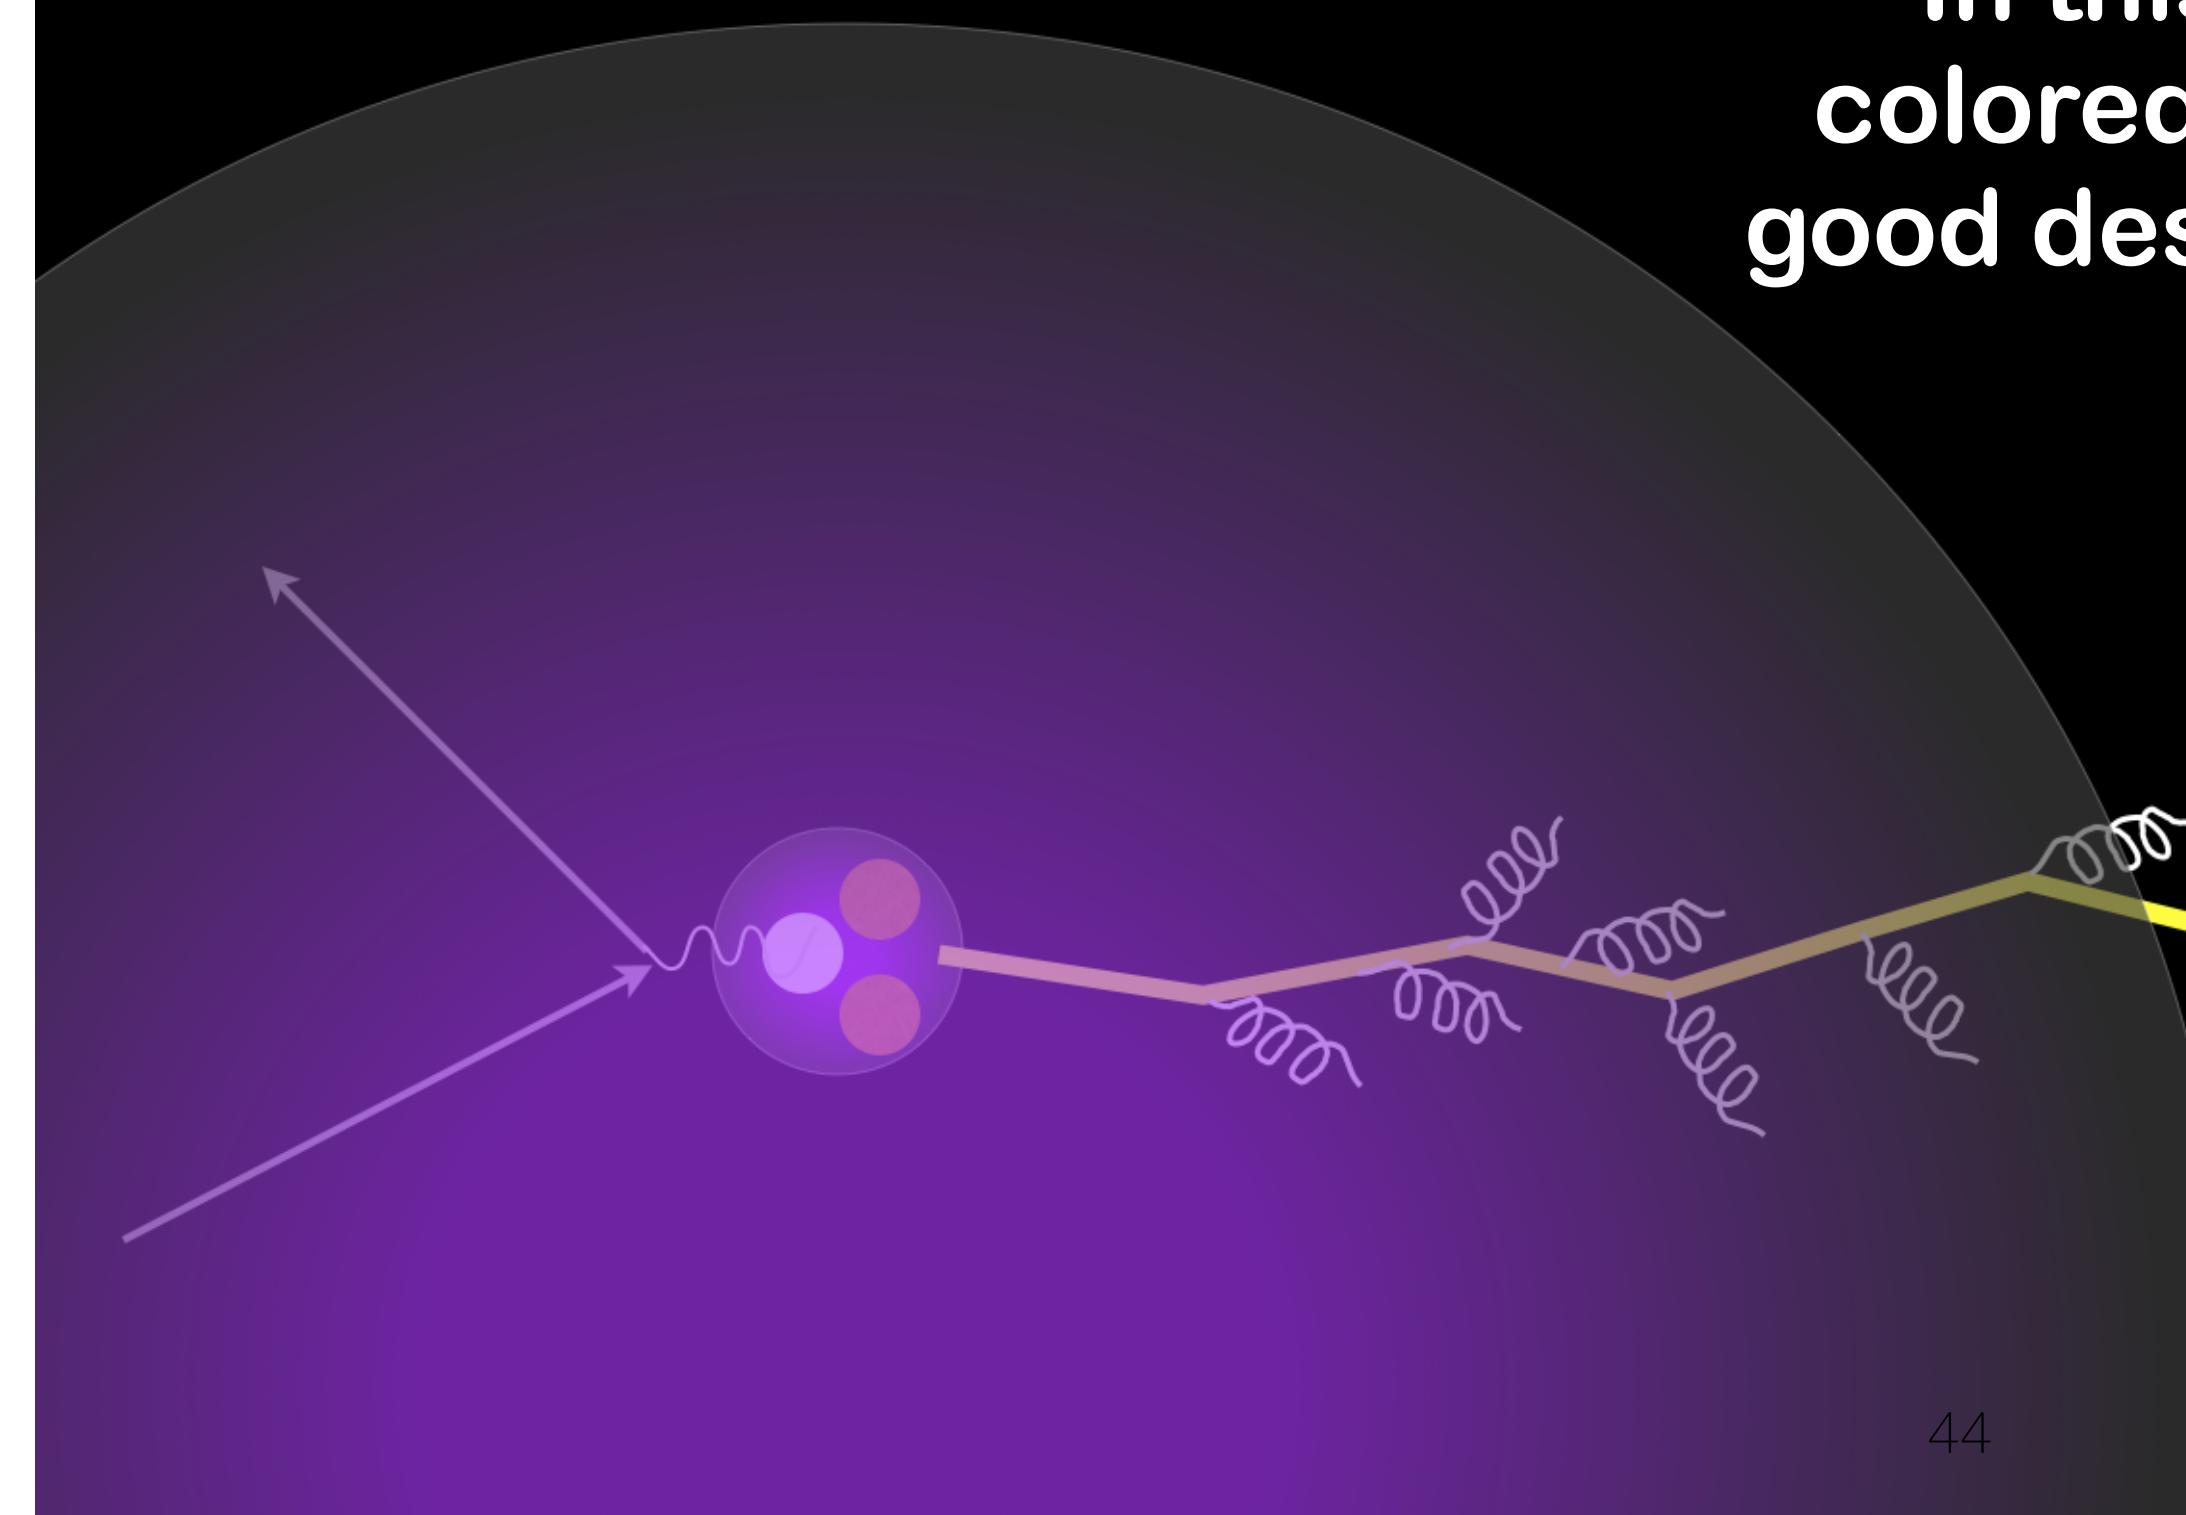

FIG. 2. Comparison between computed masses of diquark correlations and their symmetry-related meson counterparts: diquarks – (black) stars and mesons – (green) bars.

Experimental **evidence** of **diquark** **scattering** from the HERMES data for SIDIS on nuclear targets

“*Multidimensional* study of hadronization in nuclei”
arXiv:1107.3496v3 [hep-ex] 13 Sep 2011

In this picture, the first stage is a colored quark in motion. This gives a good description of producing mesons.

Interpreting HERMES Nuclear DIS DATA: MESONS

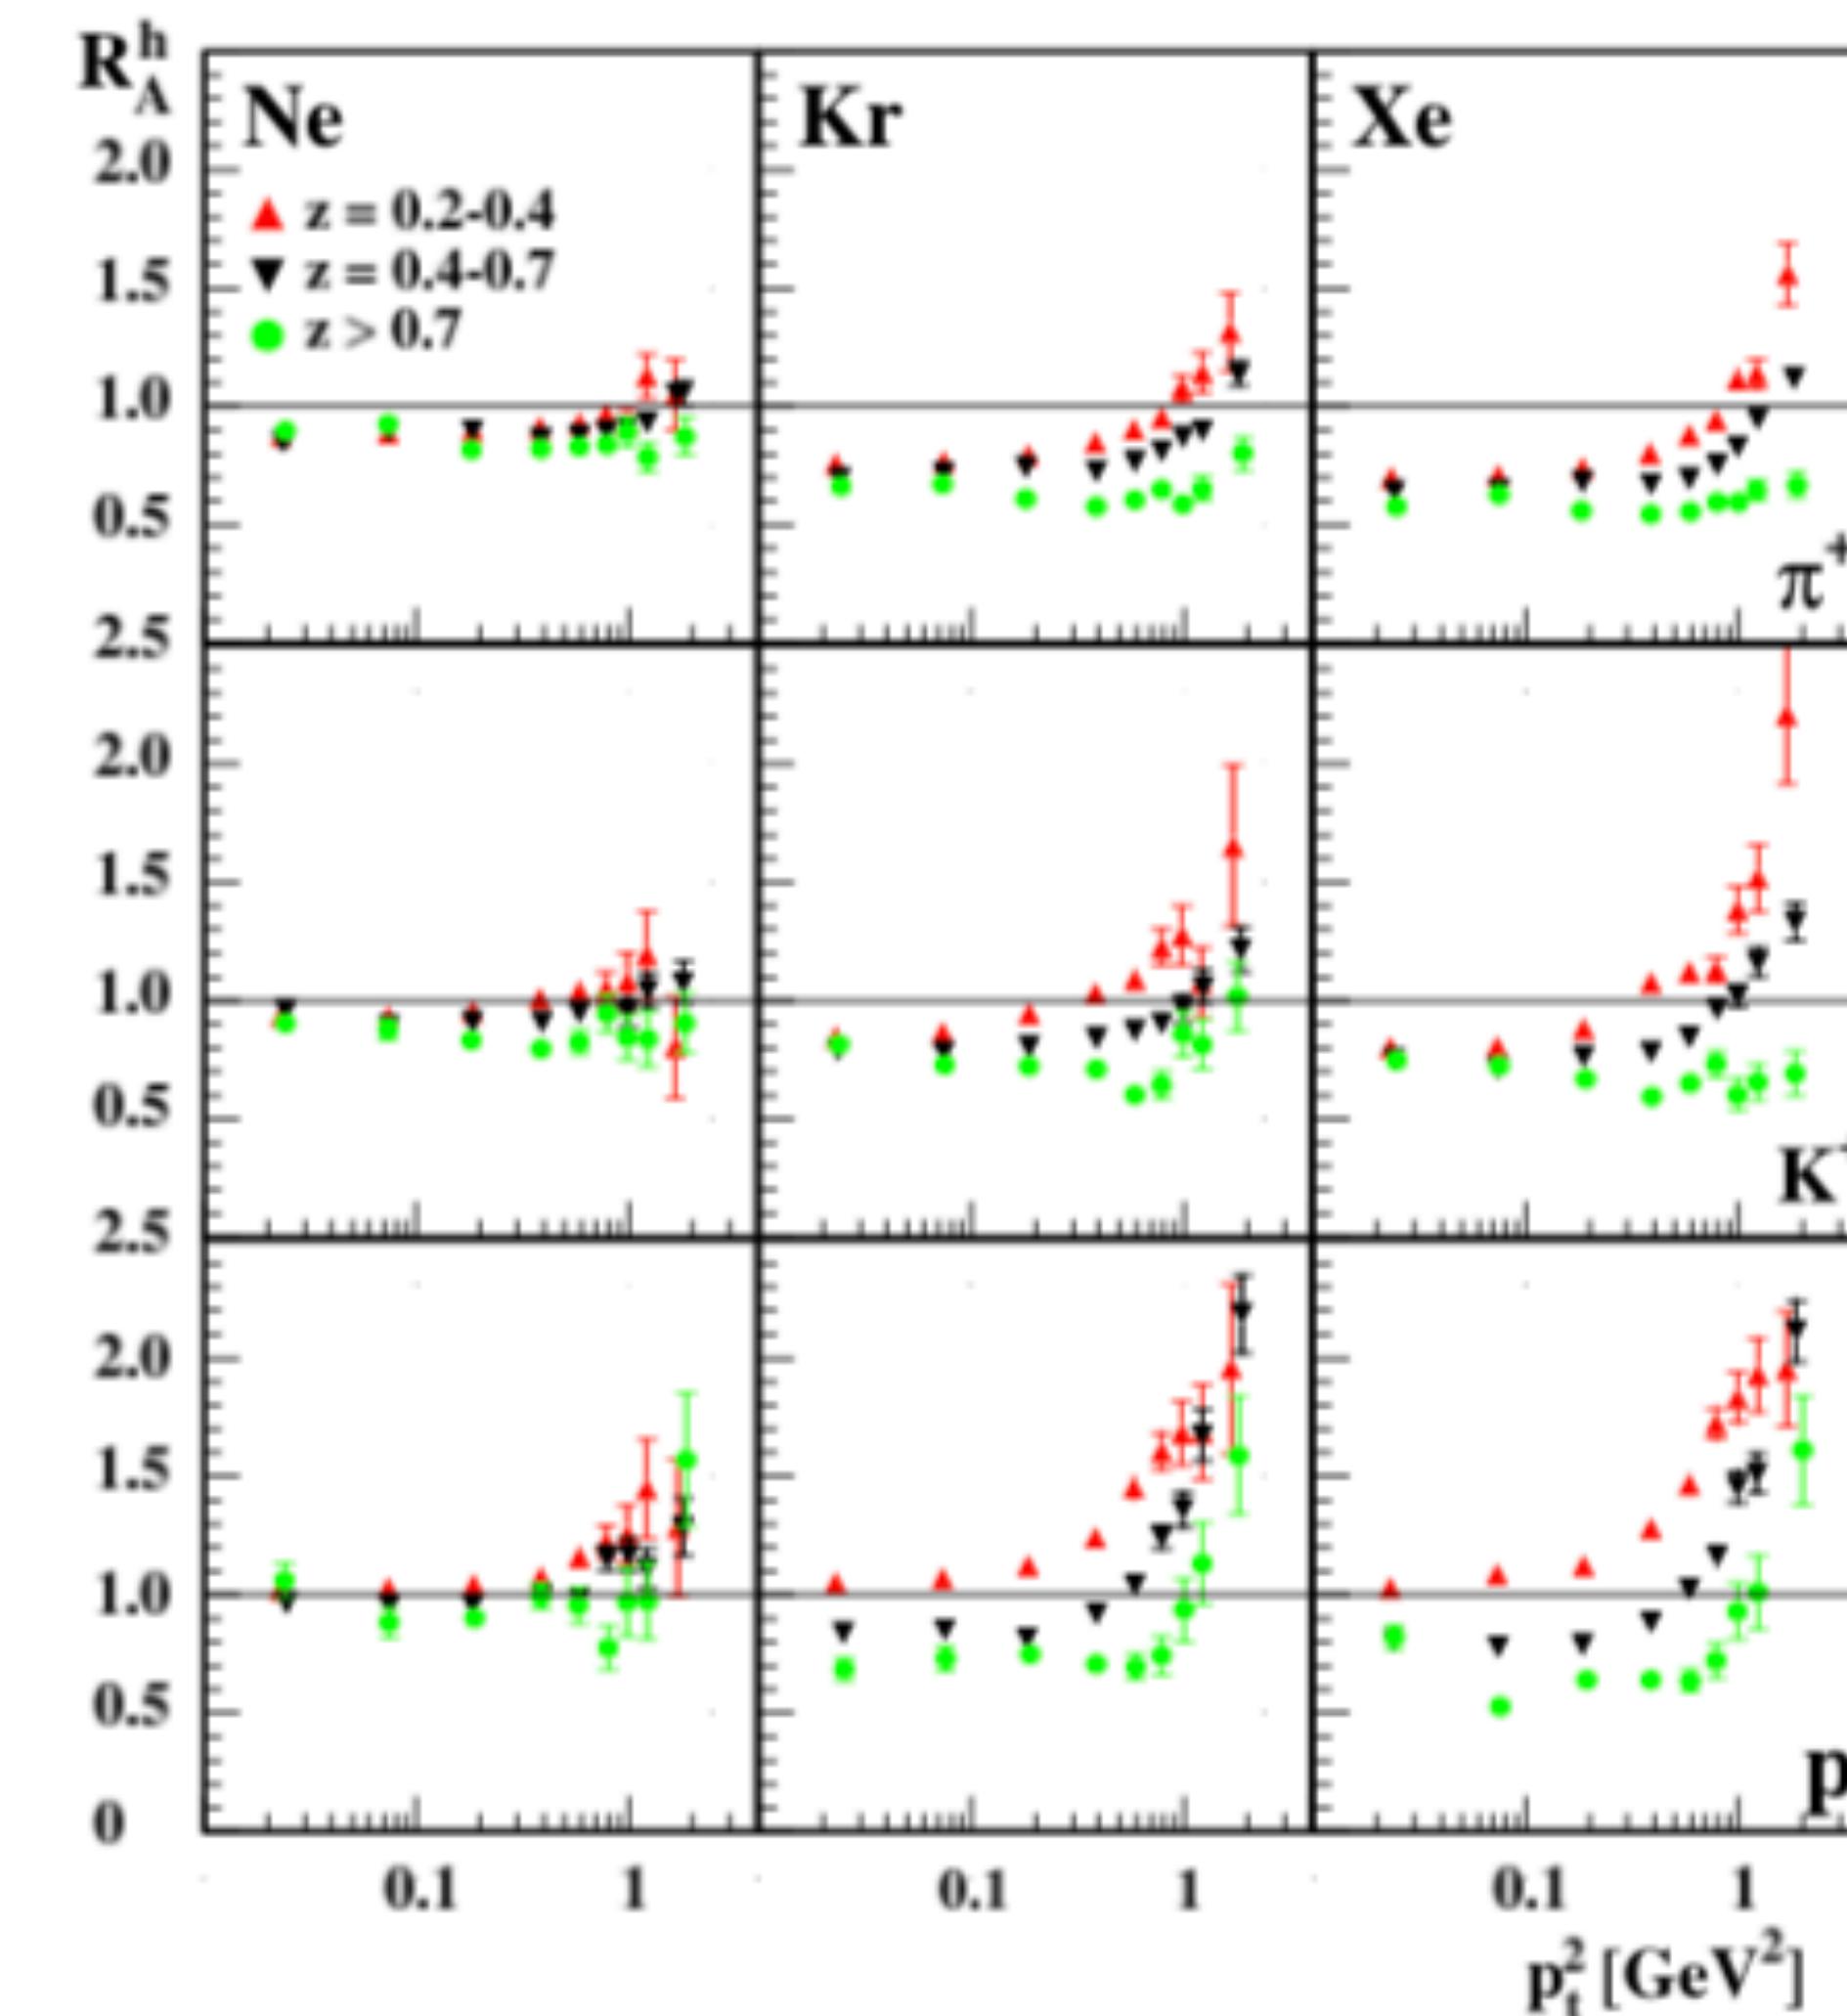

The multiplicity ratio measures effects of the nuclear medium.

“No effects” means $R=1.0$

$$R_A^h(\nu, Q^2, z, p_t^2) = \frac{\left(\frac{N^h(\nu, Q^2, z, p_t^2)}{N^e(\nu, Q^2)} \right)_A}{\left(\frac{N^h(\nu, Q^2, z, p_t^2)}{N^e(\nu, Q^2)} \right)_D}$$

Most basic indicator is pT dependence of multiplicity ratio.

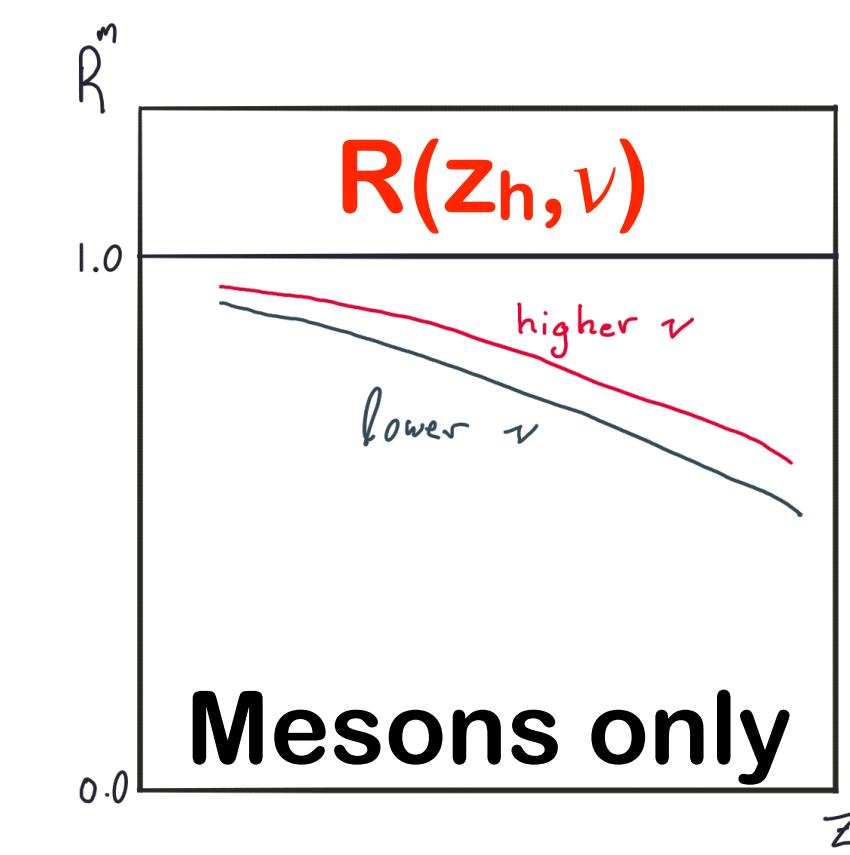

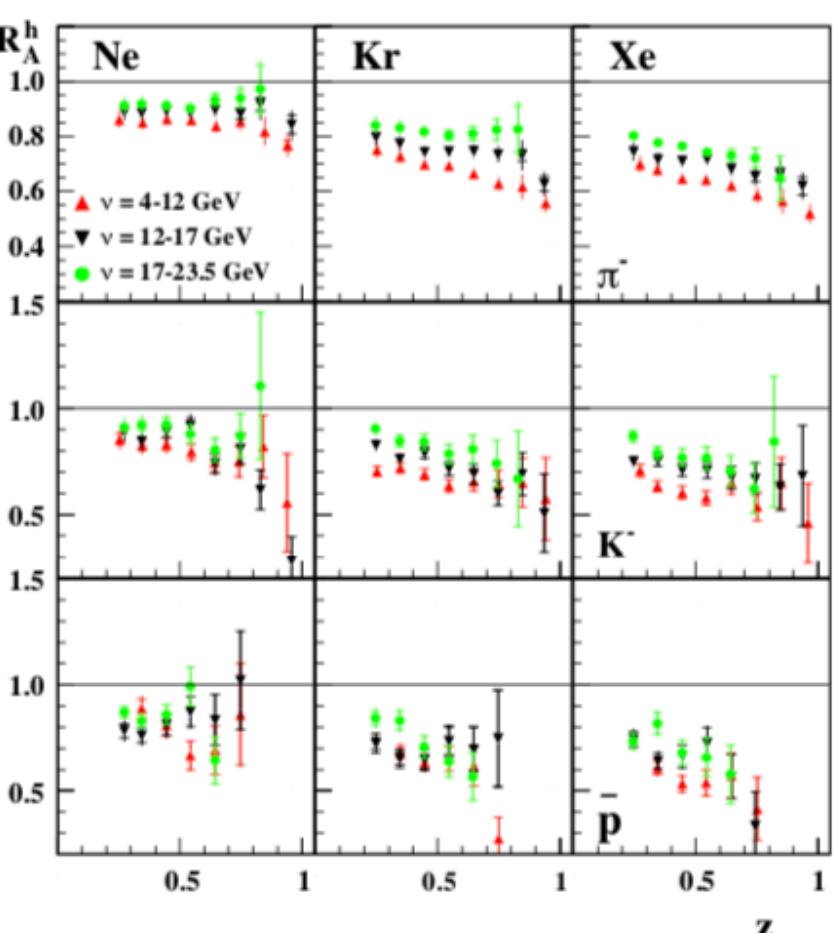

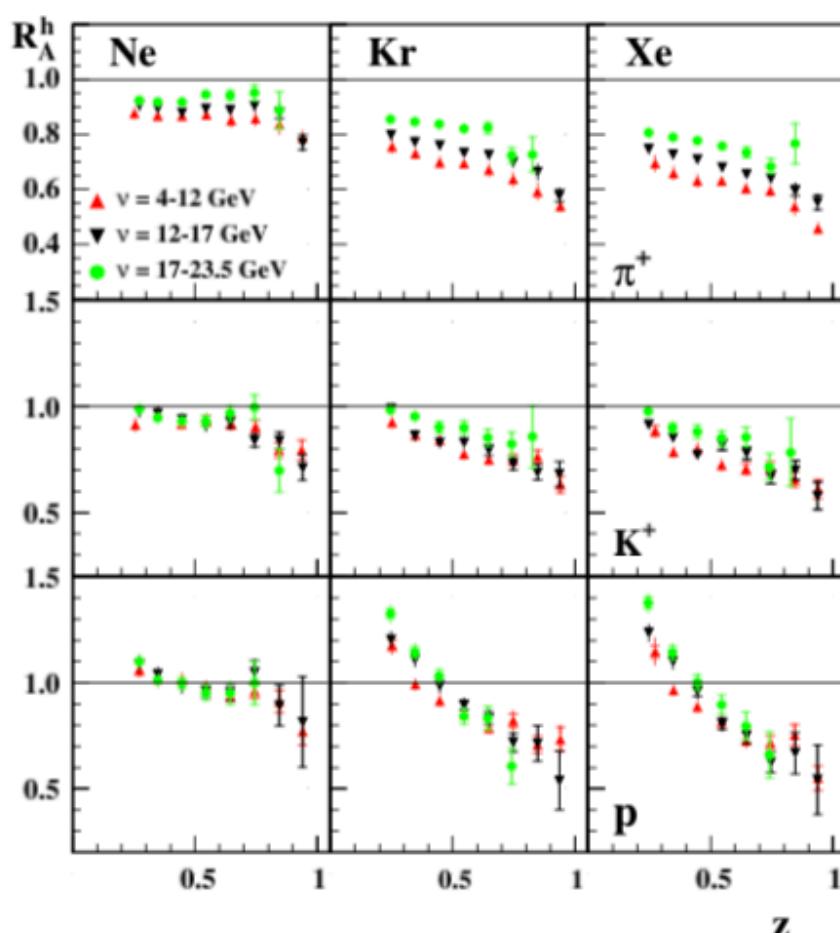

$R>1$ at high pT because particles that strongly interact with the medium acquire more pT than those that don't interact as much.

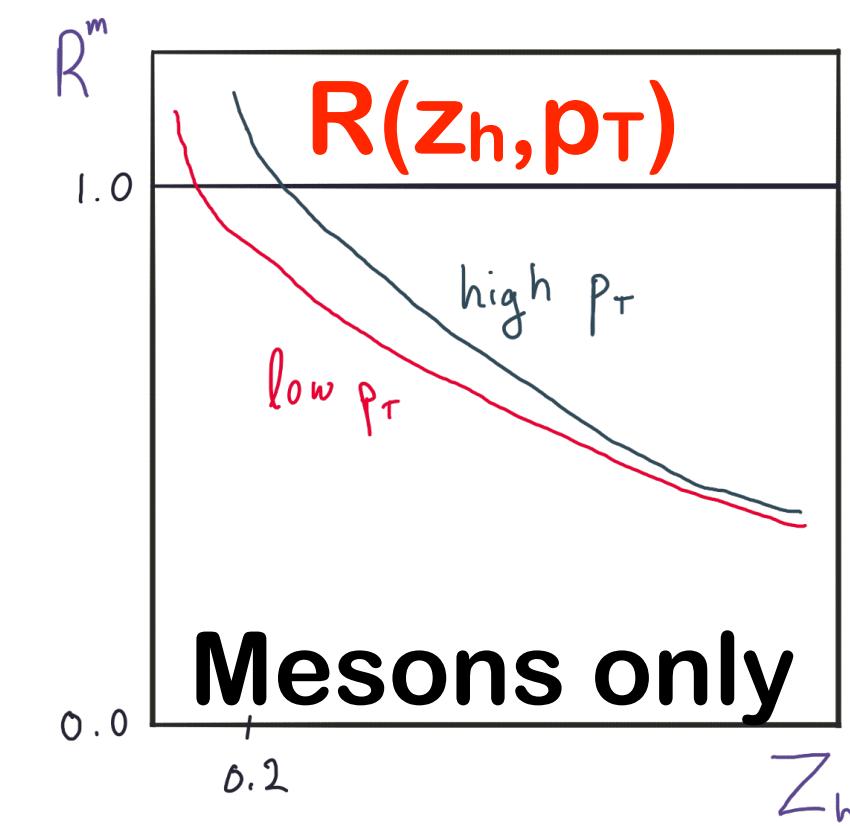

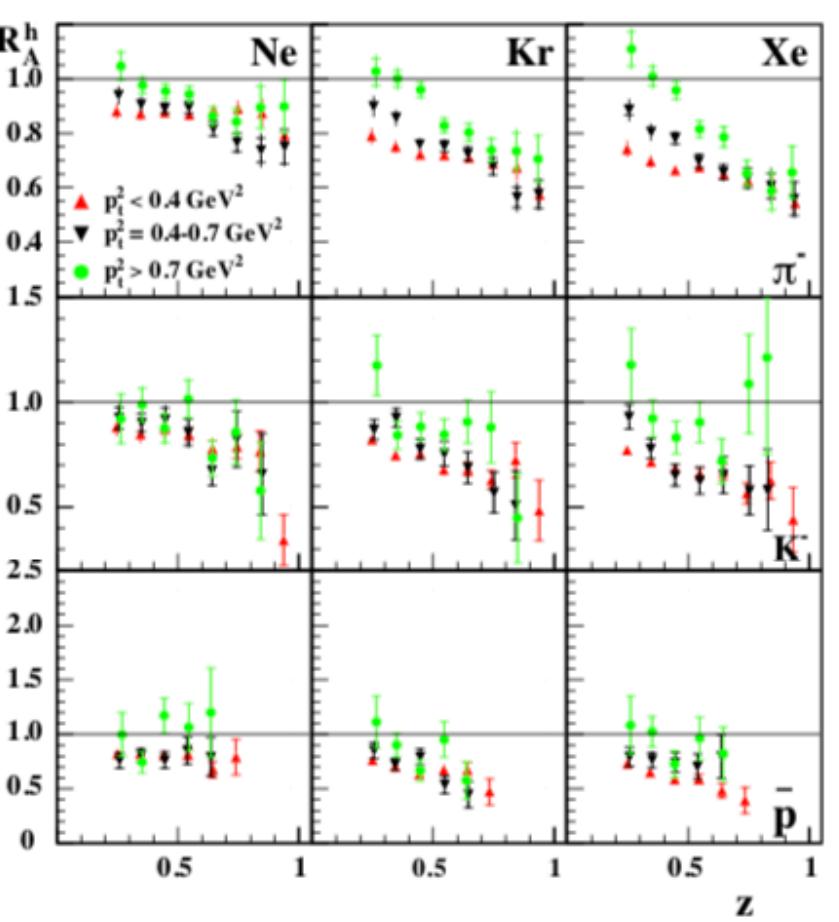

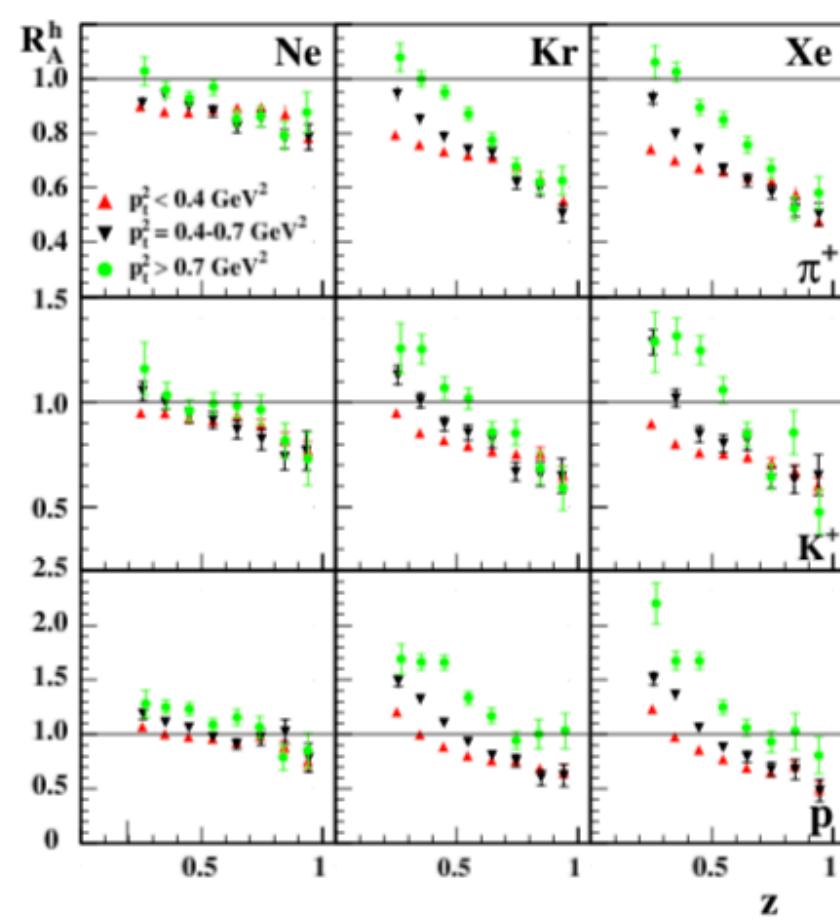

“Interact” = hadronic interaction of forming hadrons, + quark energy loss.

Empirically, from these plots, low-z mesons acquire more pT than high-z.

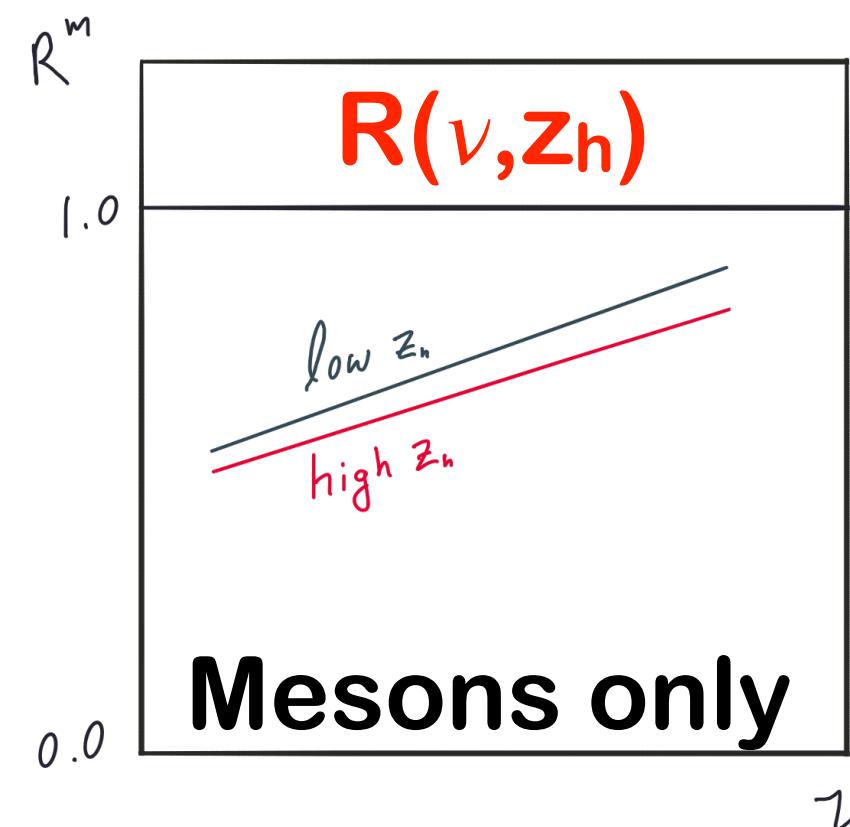

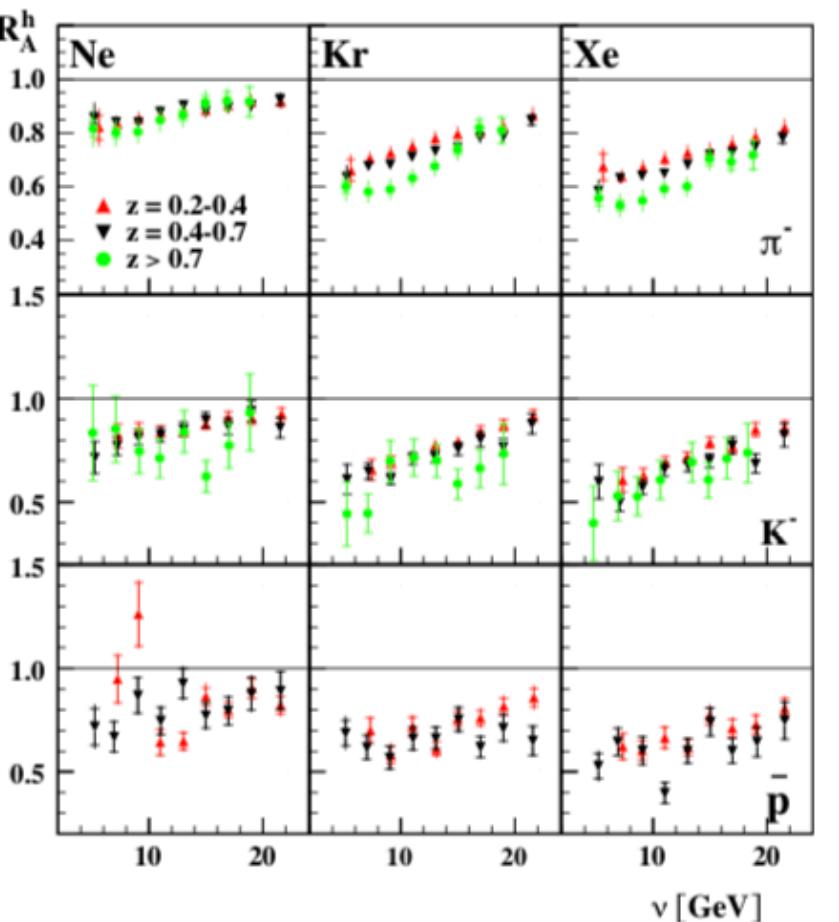

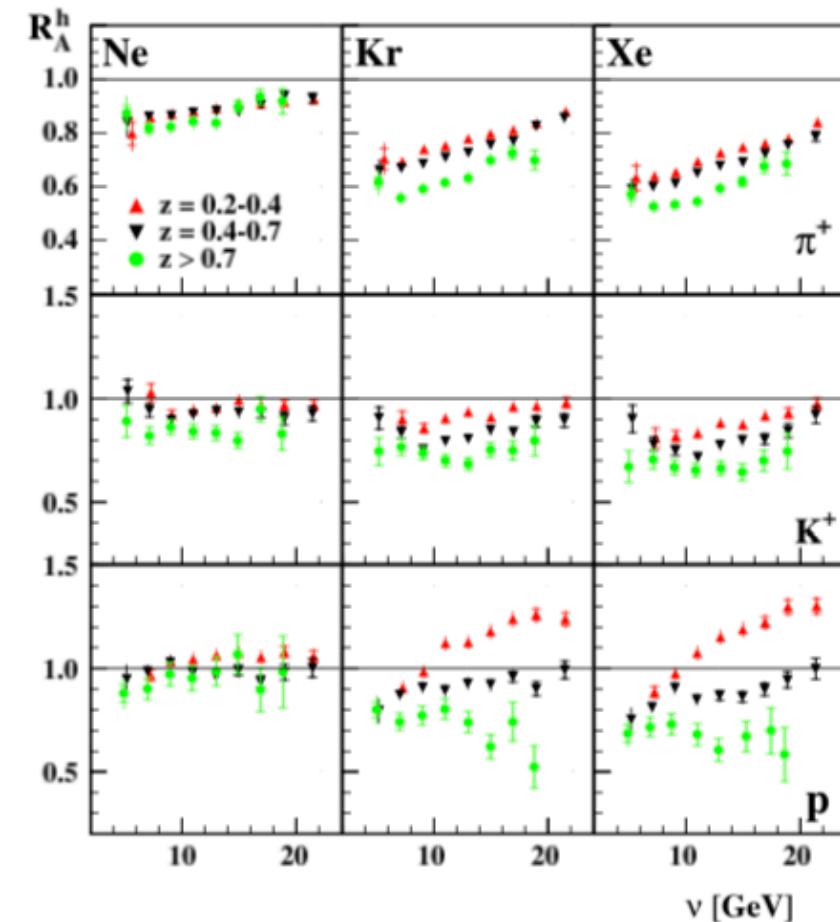

Enhancement at high pT mostly caused by hadronic interactions at low z.

Integrated over pT,
so always < 1 .
At higher ν , less
attenuation because
of time dilation of
quark lifetime

Not integrated over
pT, so can exceed 1.
Exceeds 1 faster for
higher pT, so
crossing point is pT
dependent.

Time dilation is
proportional to ν .
Slow approach to 1.0
at infinite ν . Quark
lifetime goes to zero at
high z , so high z is
attenuated more.

So far, we have a reasonable **qualitative** interpretation for **mesons** that explains multi-dimensional behavior completely.

BUT: mesons don't have diquarks

Let's see if we can understand HERMES baryon data

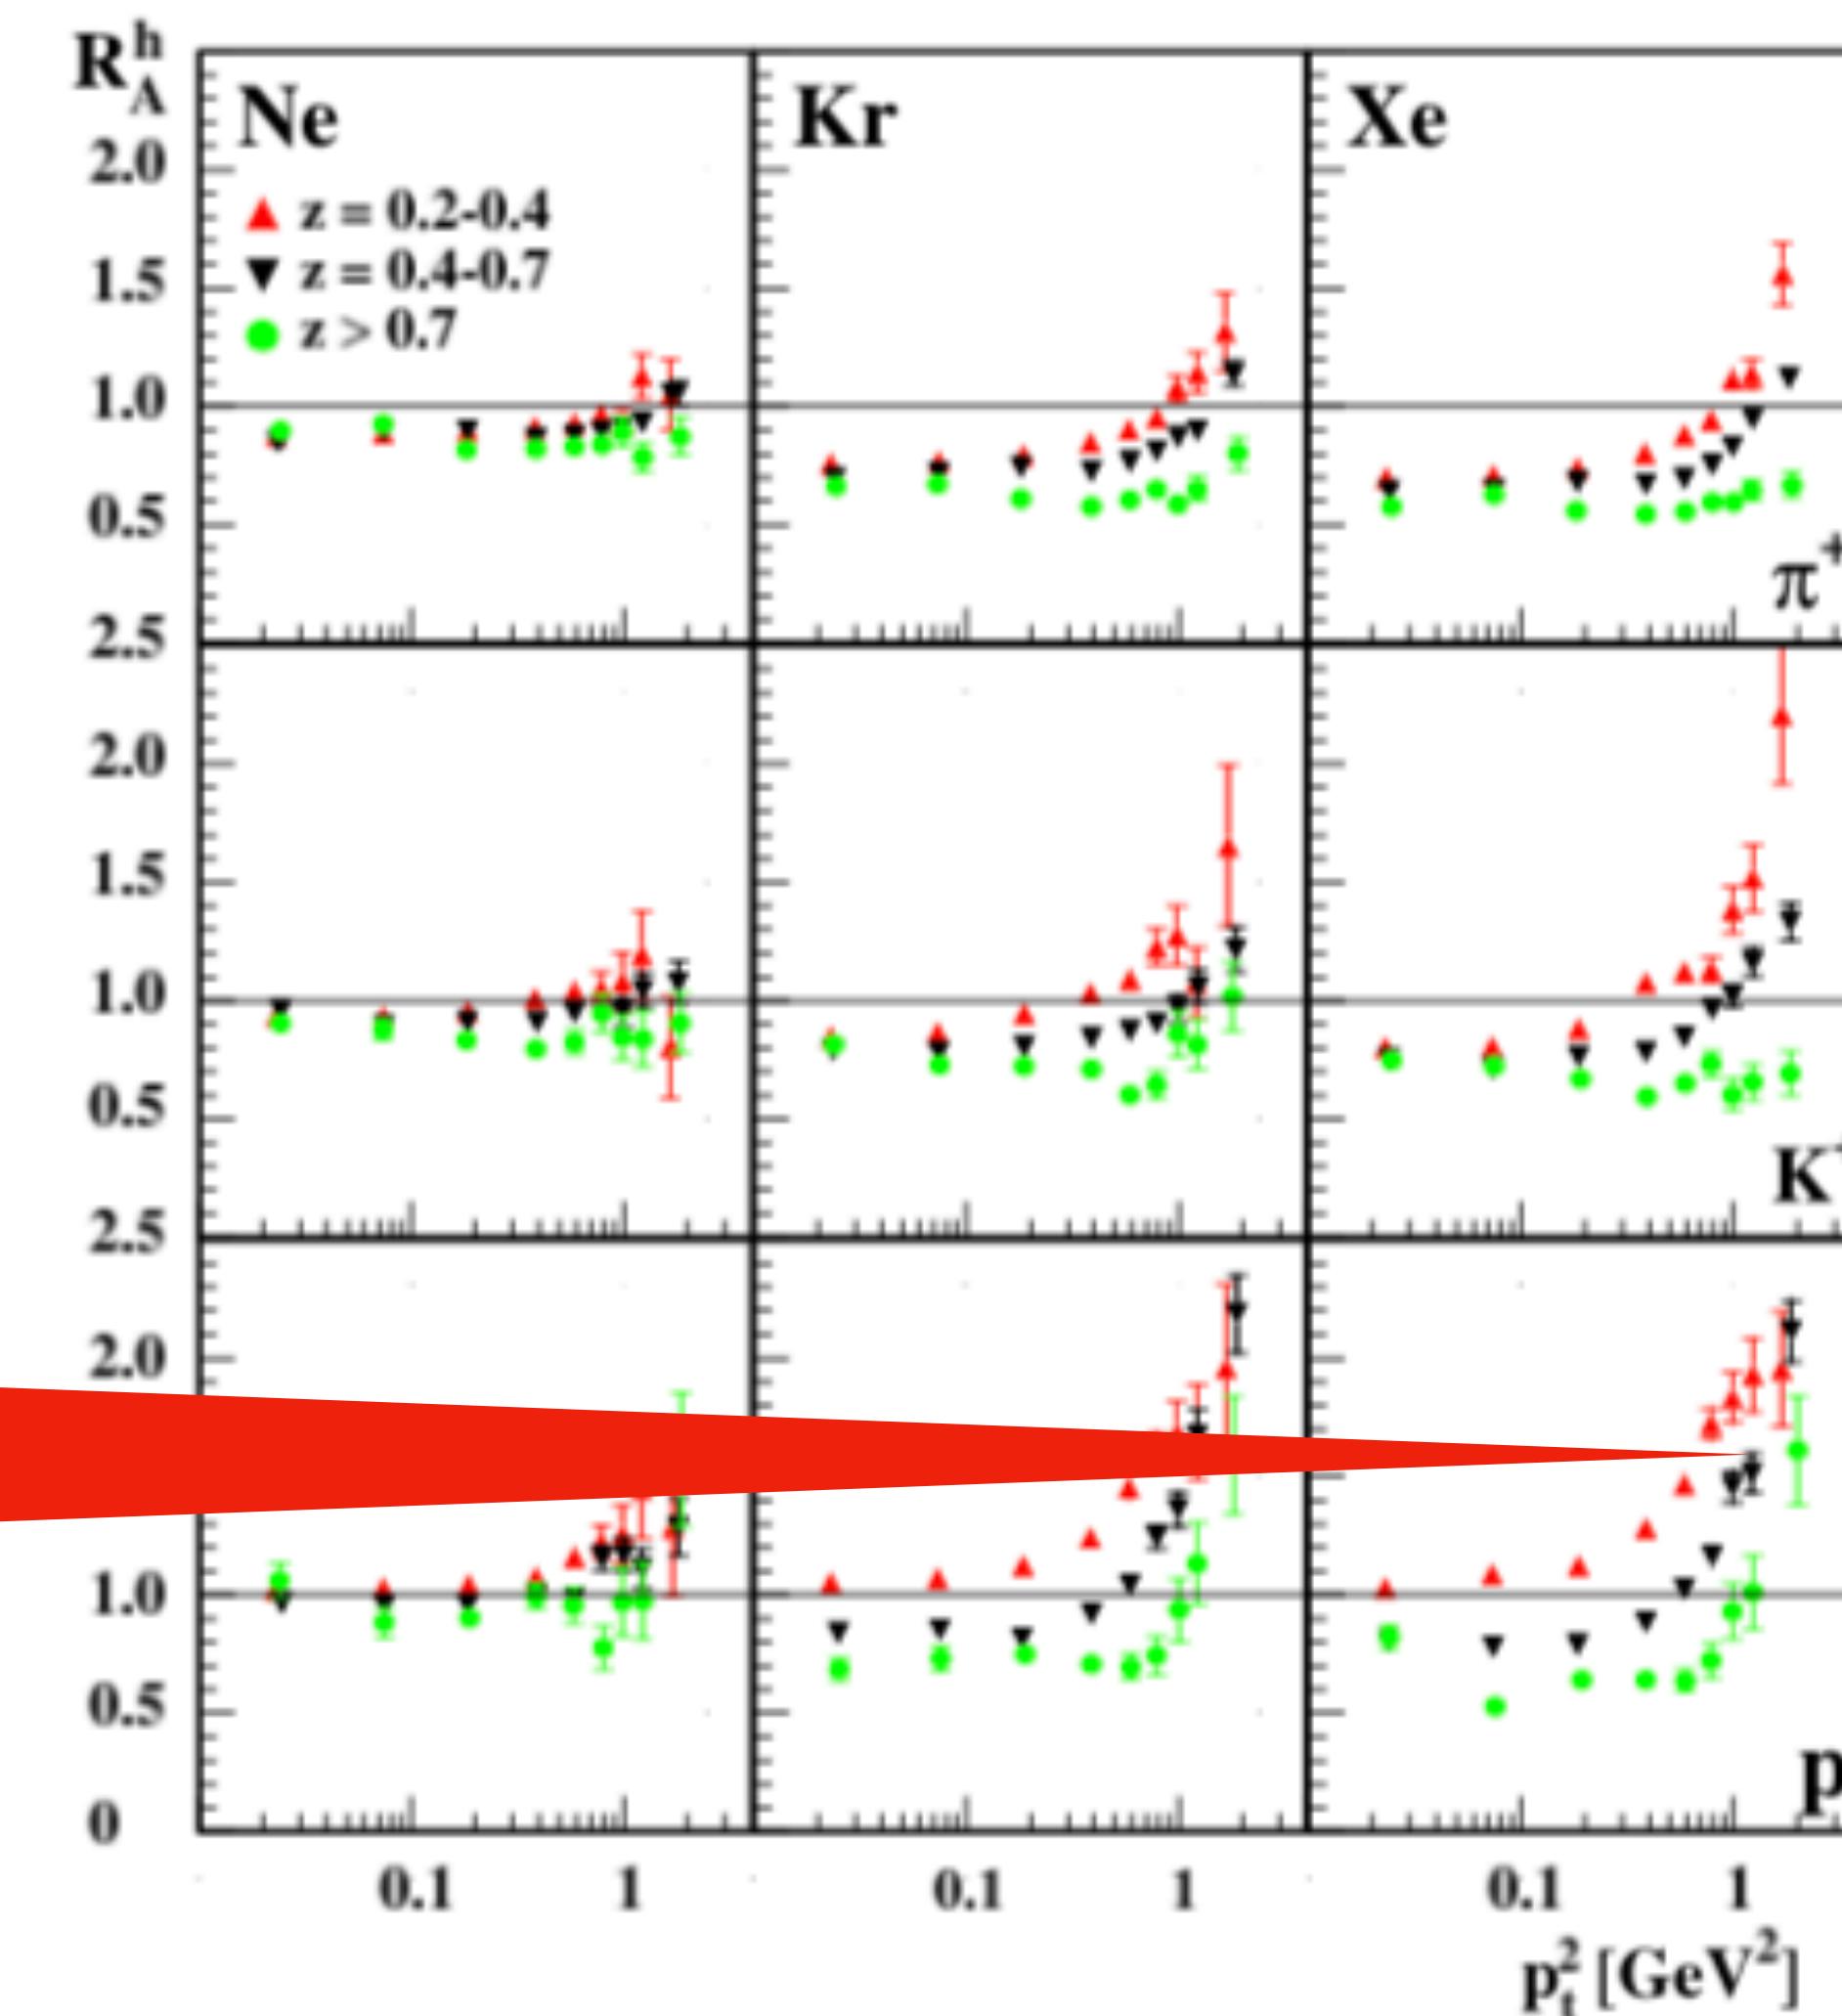

Interpreting HERMES Nuclear DIS DATA: MESONS

The multiplicity ratio measures effects of the nuclear medium.
“No effects” means $R=1.0$

$$R_A^h(\nu, Q^2, z, p_t^2) = \frac{\left(\frac{N^h(\nu, Q^2, z, p_t^2)}{N^e(\nu, Q^2)} \right)_A}{\left(\frac{N^h(\nu, Q^2, z, p_t^2)}{N^e(\nu, Q^2)} \right)_0}$$

The ordering in z seen for mesons disappears at high pT for protons.

Strong interaction
occurs at all values of z .

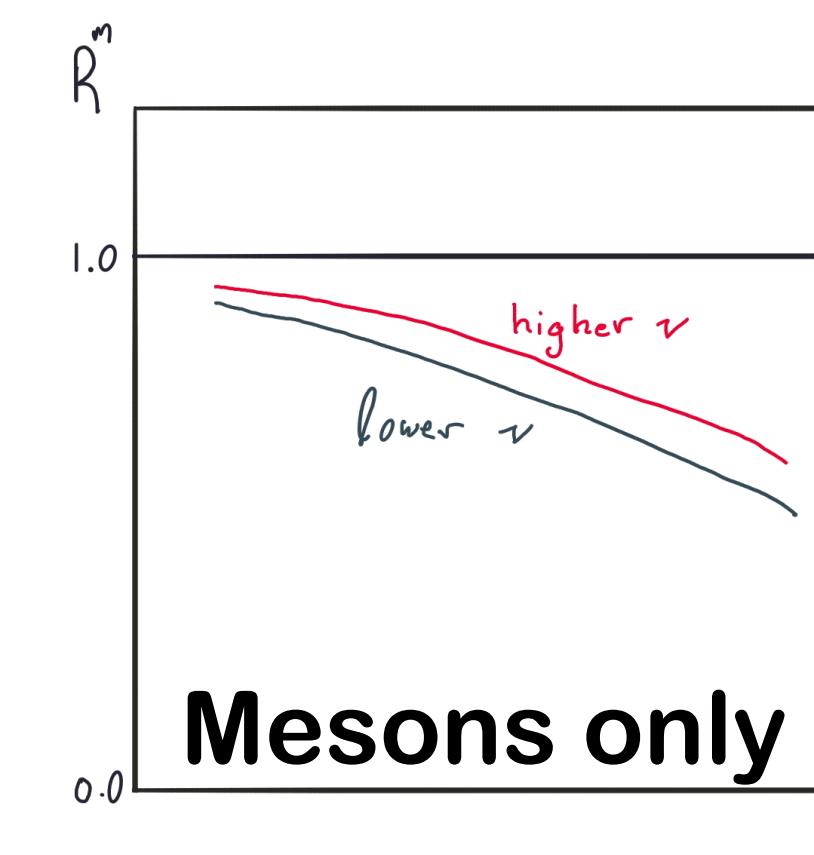

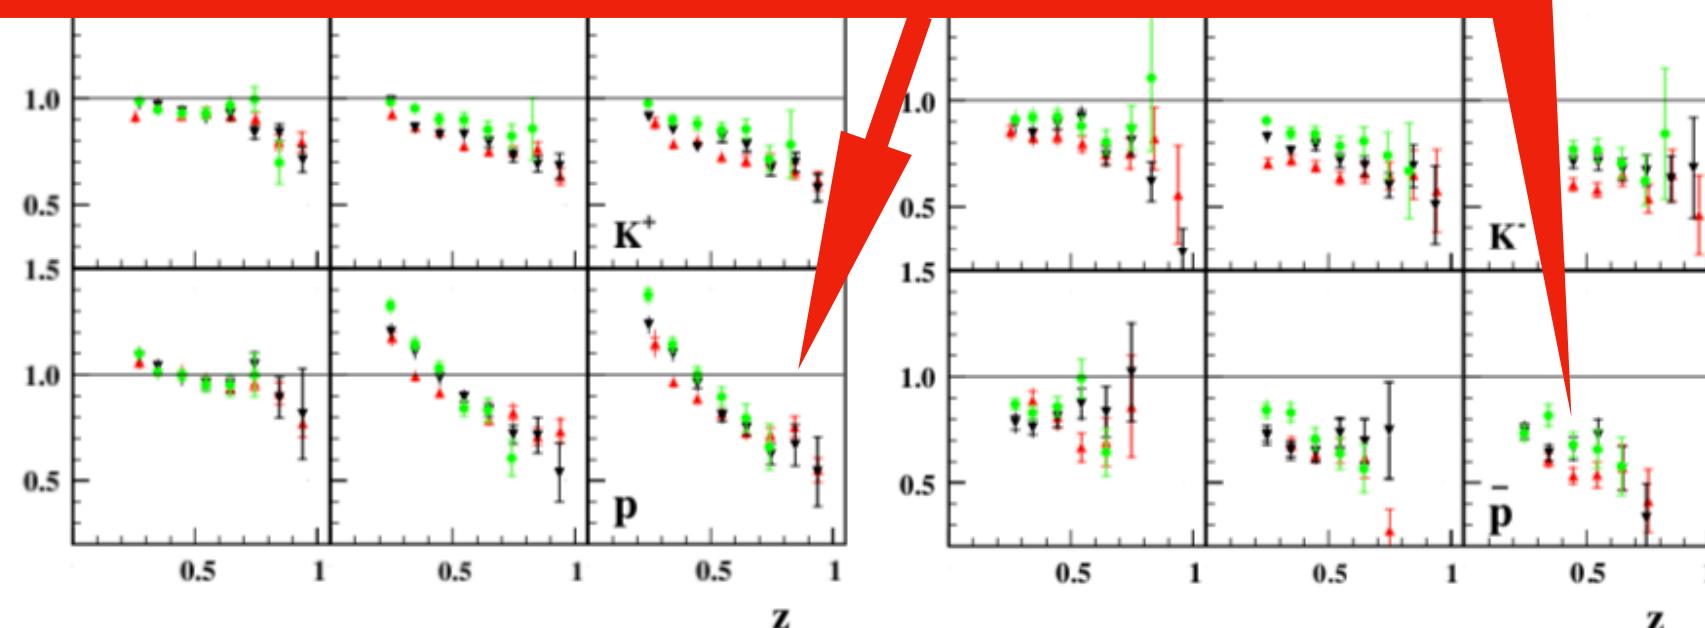

Interact → hadronic interaction of forming hadrons, + quark energy loss.

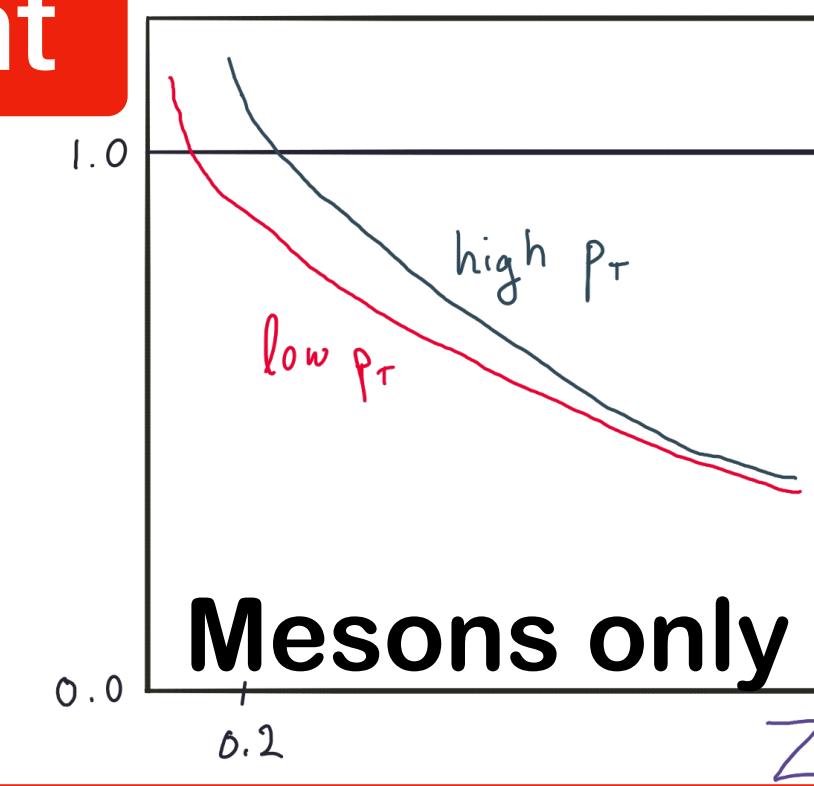

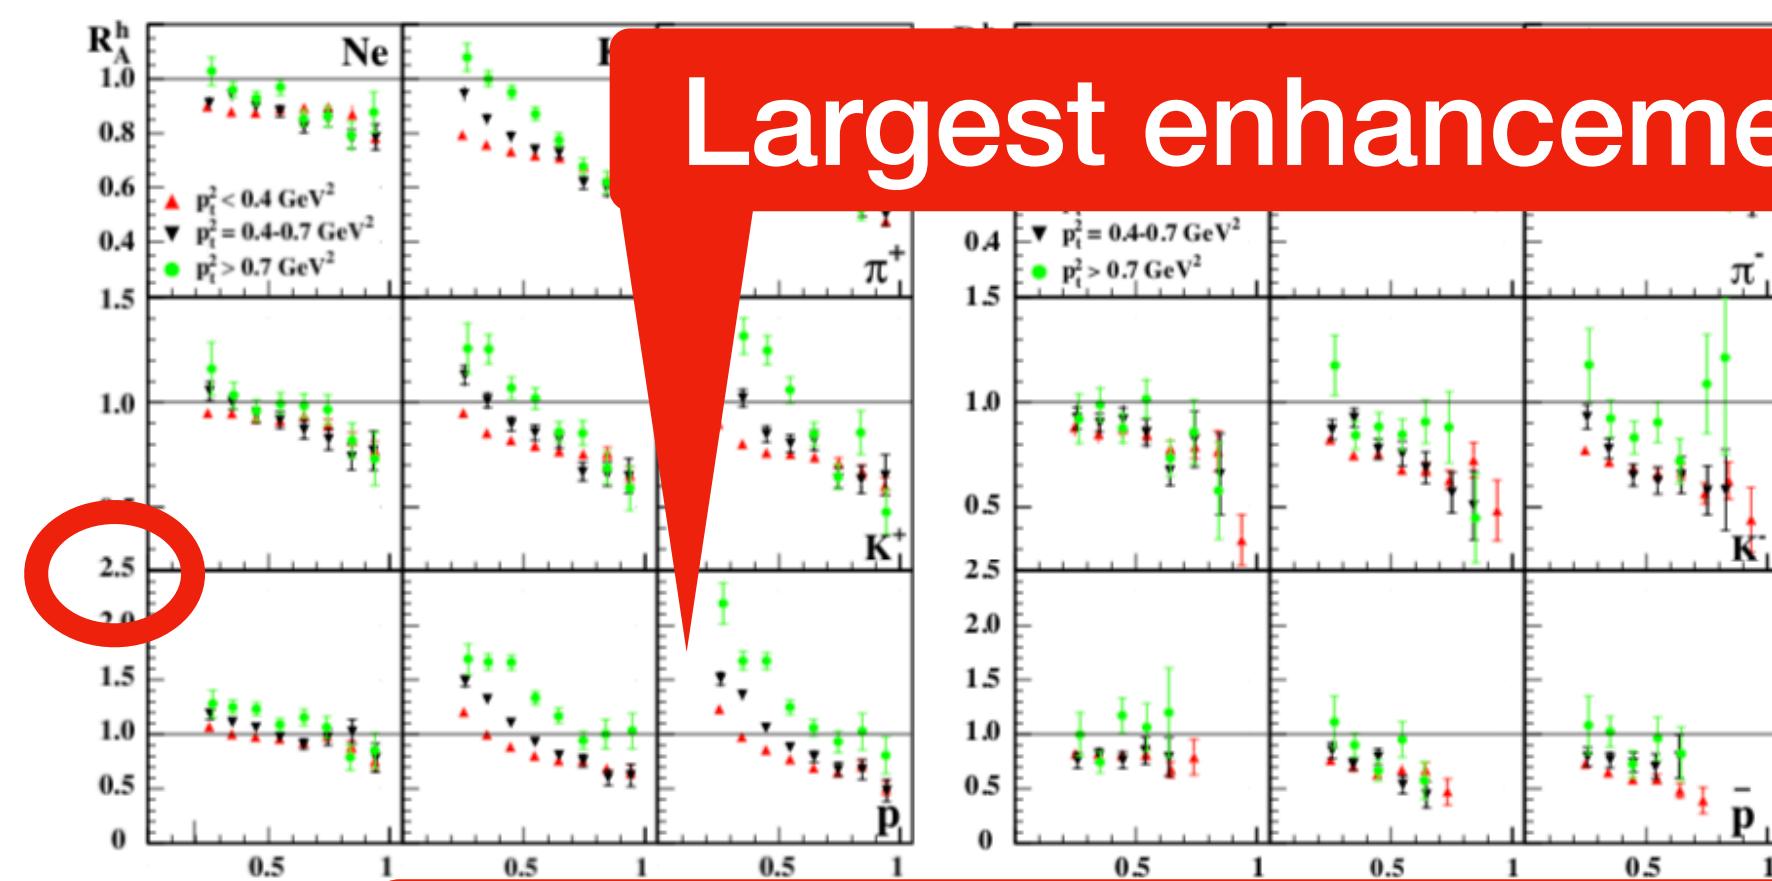

Empirically, from these plots, low- z mesons acquire more pT than high- z .

Enhancement at high pT mostly caused by hadronic interactions at low z .

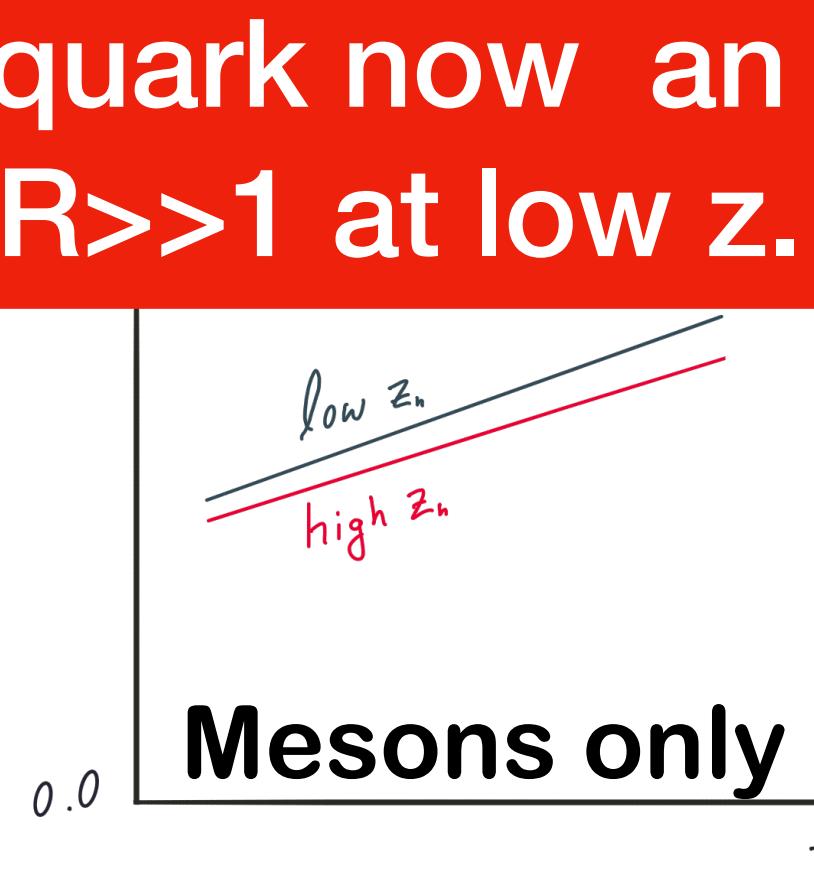

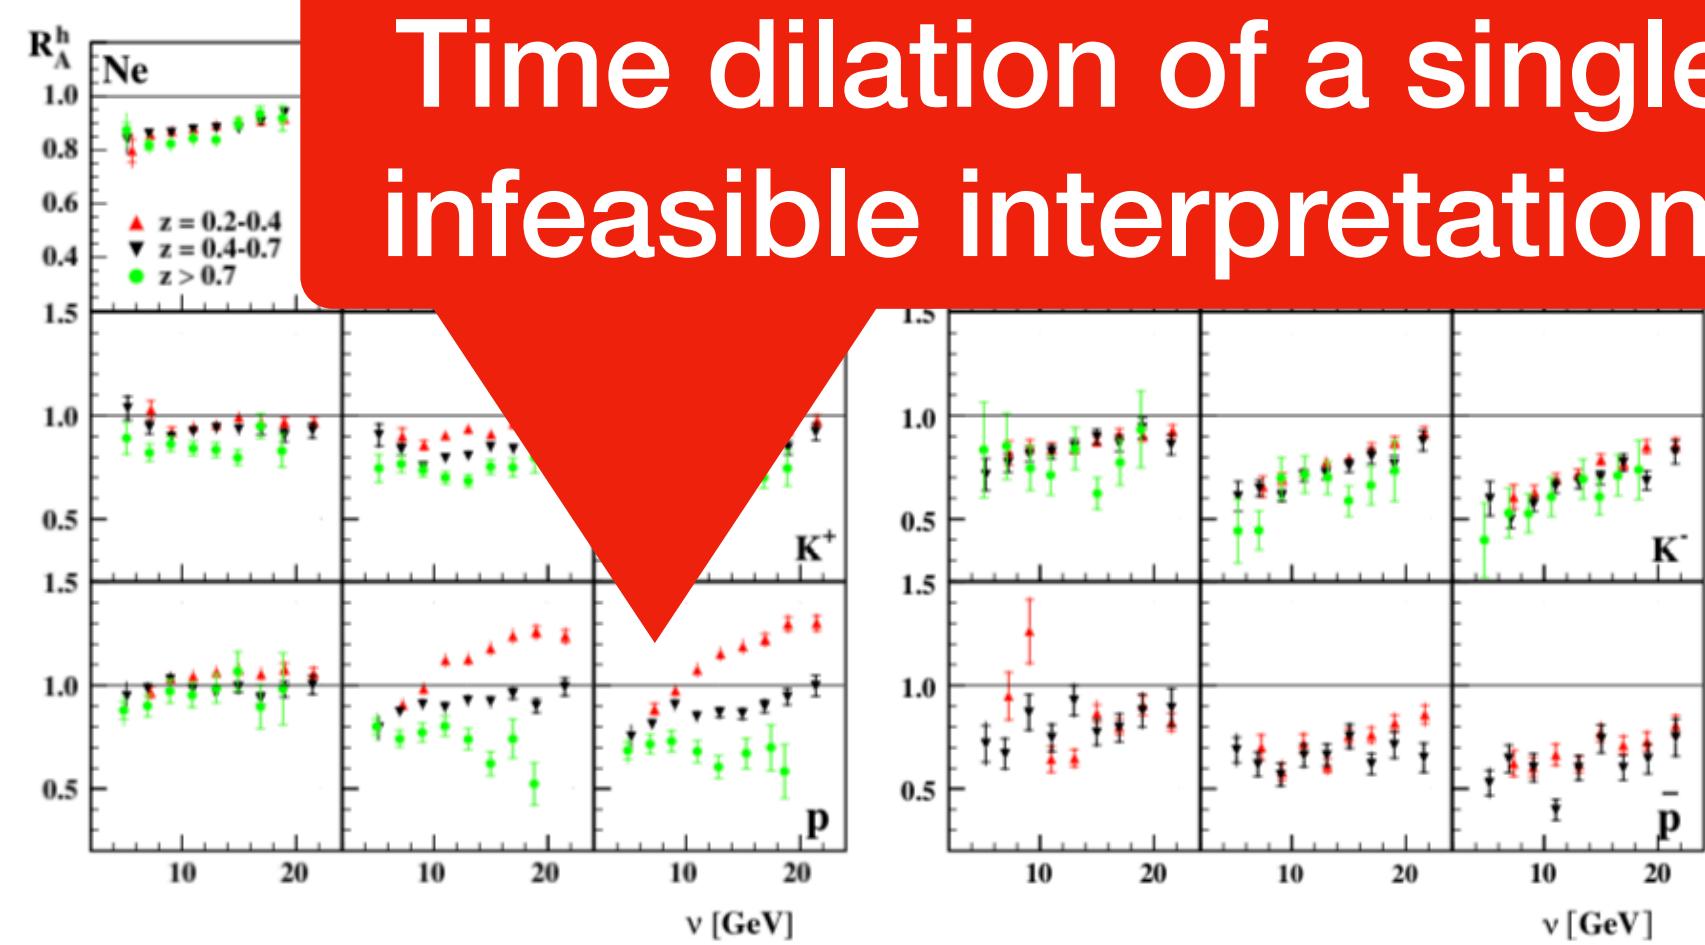

Protons and antiprotons act completely differently

Integrated over p_T , so always < 1 .
At higher ν_u , less attenuation because of time dilation of quark lifetime

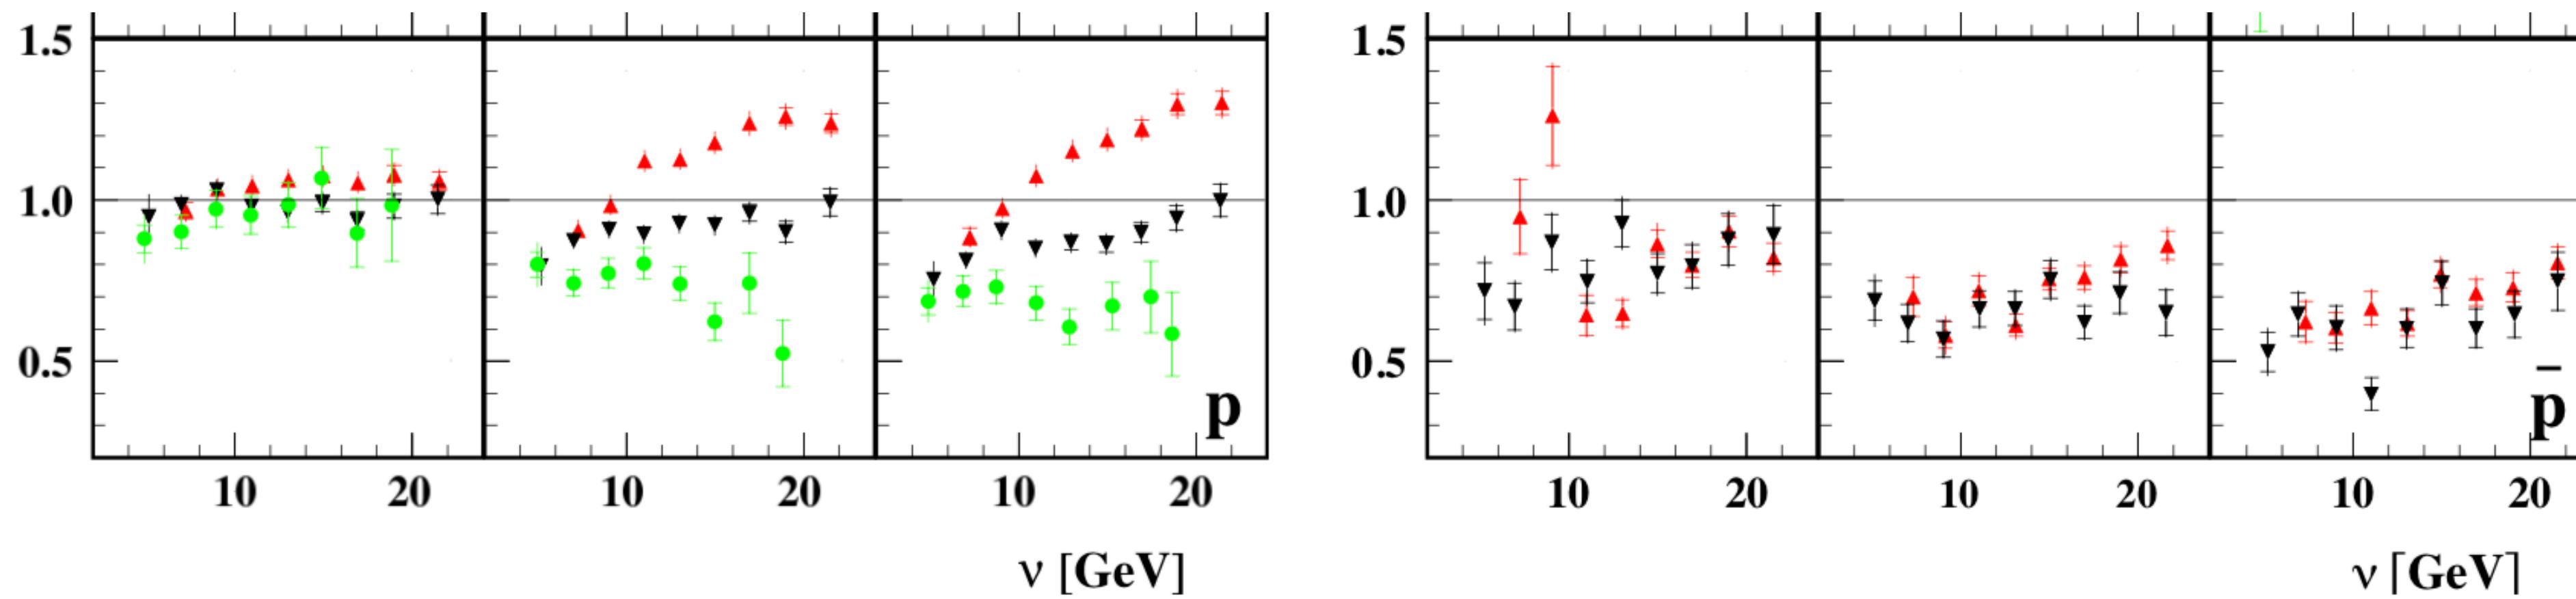

Not integrated over p_T , so can exceed 1.
Exceeds 1 faster for higher p_T , so crossing point is p_T dependent.

Time dilation is proportional to ν_u .
Slow approach to 1.0 at infinite ν_u . Quark lifetime goes to zero at high z , so high z is attenuated more.

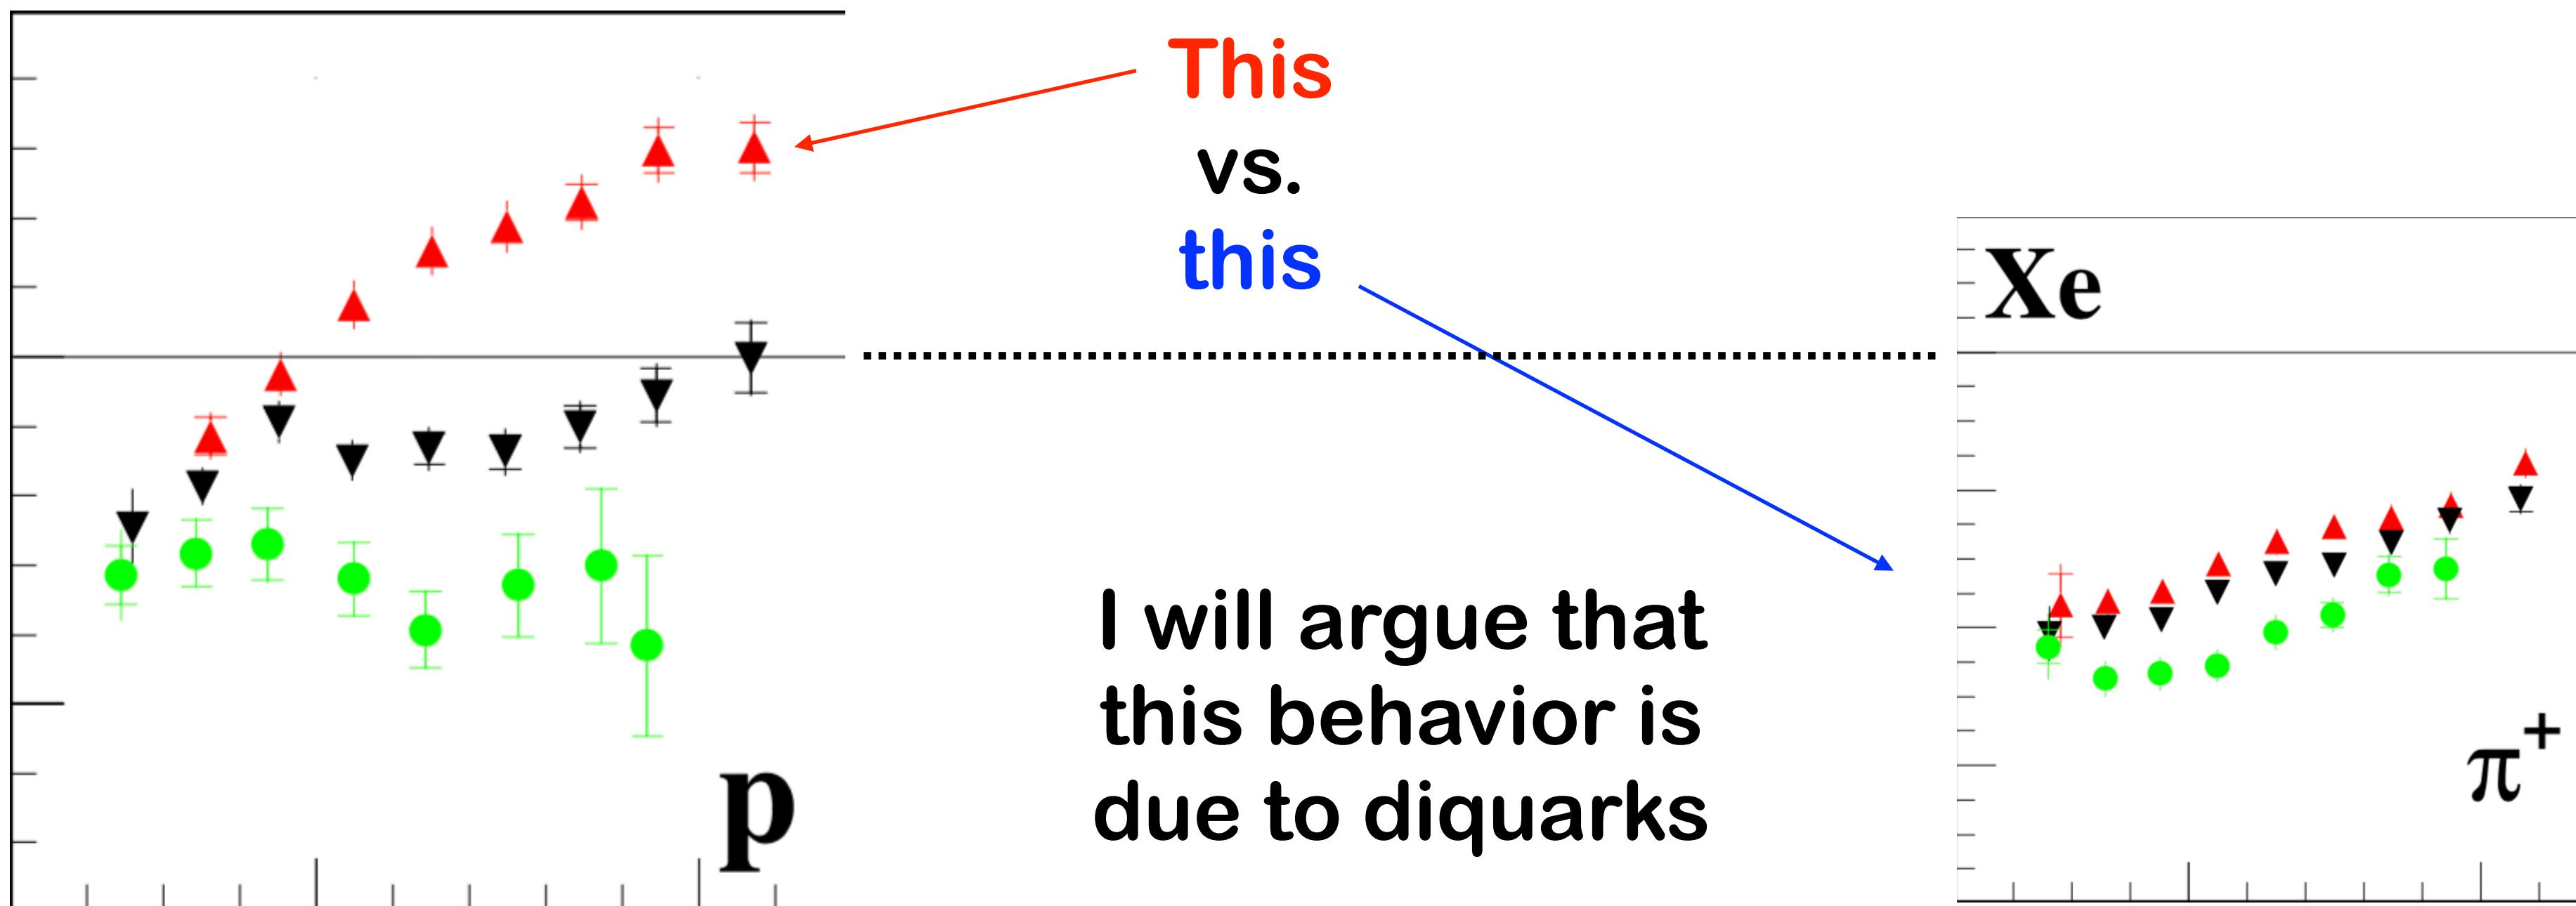

HERMES Proton Multiplicity Ratios

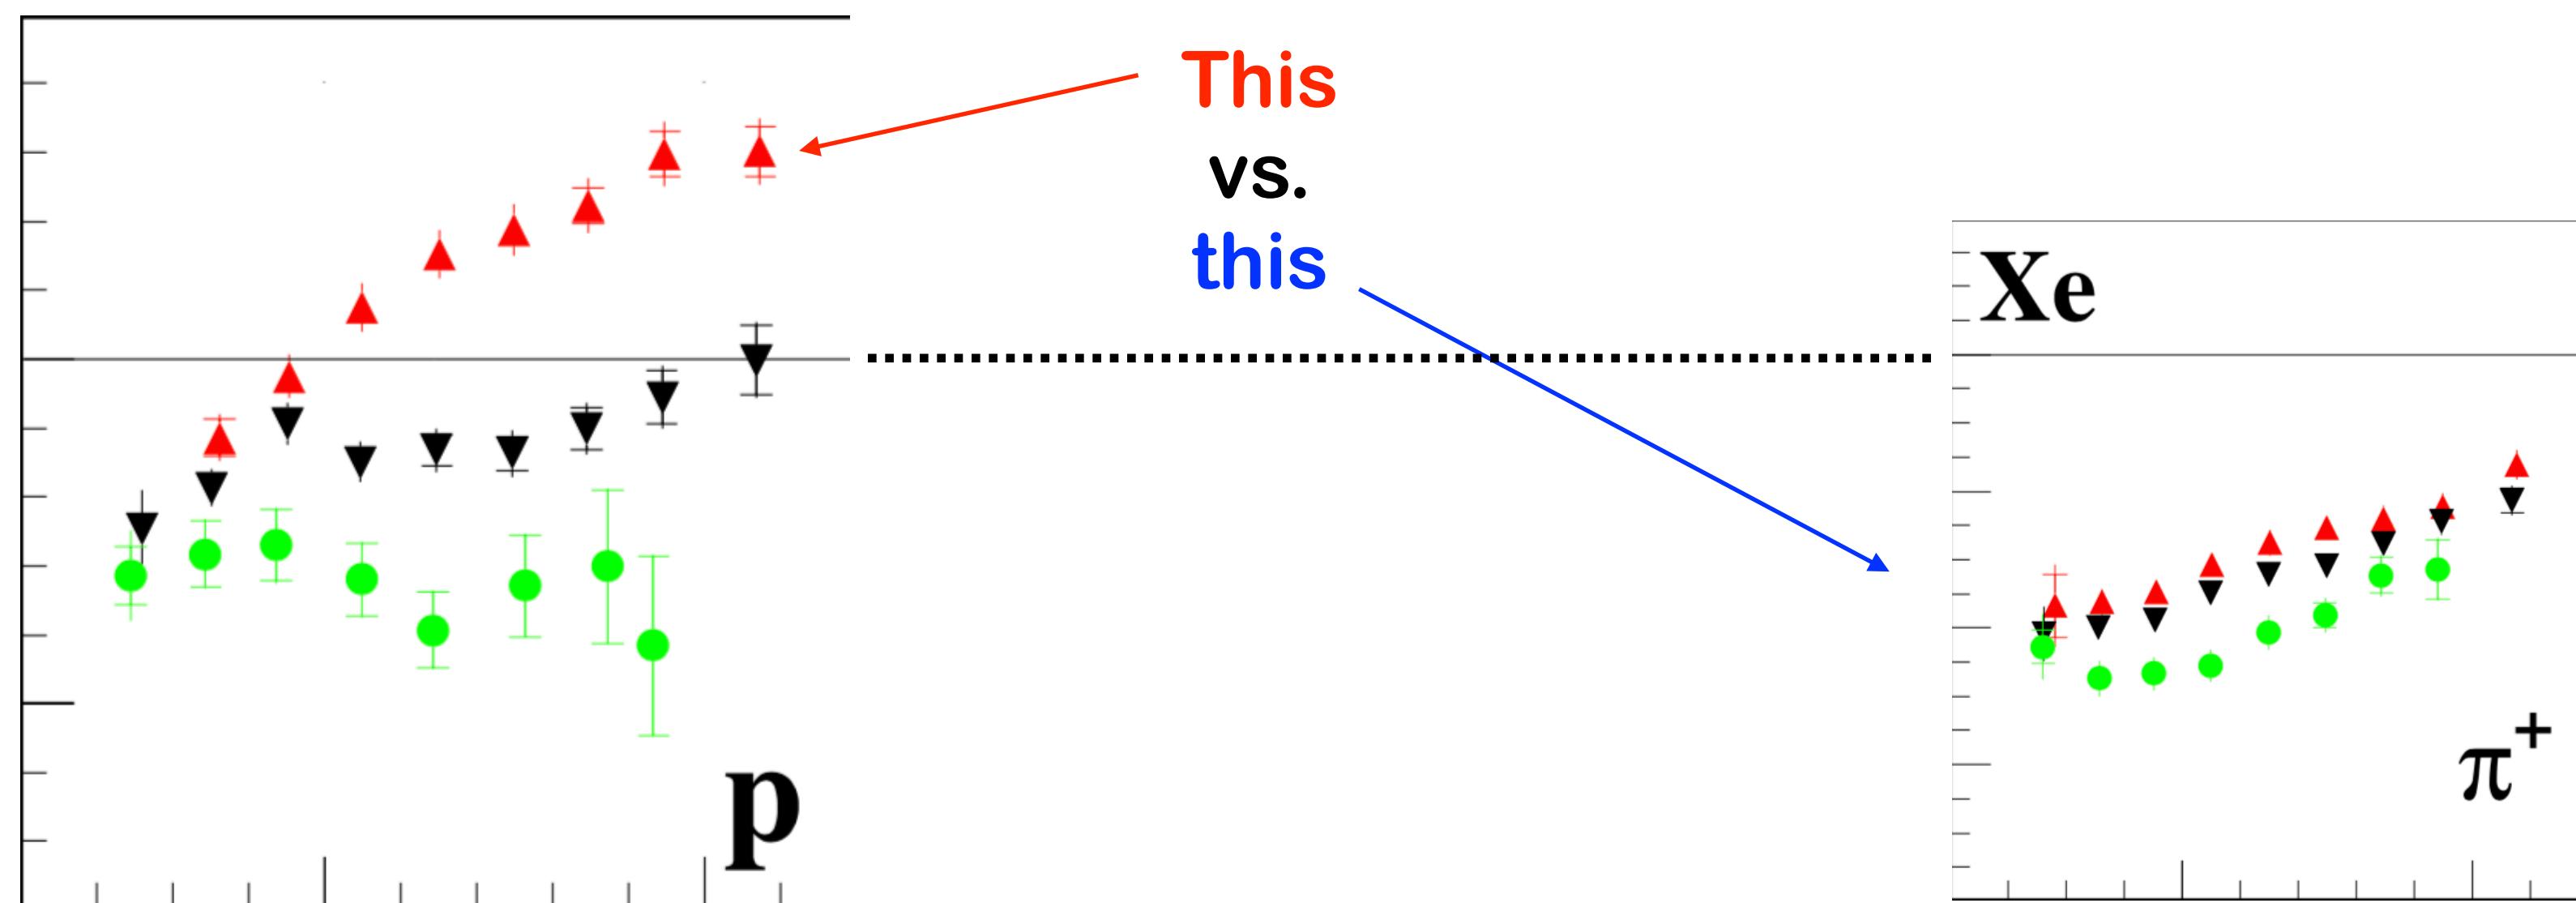

\blacktriangle $z = 0.2-0.4$
 \blacktriangledown $z = 0.4-0.7$
 \bullet $z > 0.7$

proton (left) and antiproton (right) are totally different

Proton multiplicity ratios qualitatively different from mesons.

HERMES paper explanation: FSI are “knocking out protons.” **Maybe.** But, @ high W and Q^2 , = virtual photon strikes **one** quark: need to make a pion in-medium to knock out a proton

But maybe it could be diquarks knocking them out. Diquark “size” must be similar to that of a proton (mass is similar to and larger than that of a proton).
= diquark color field much more extended in space

Test this hypothesis: CLAS preliminary nDIS data for Lambda Baryons

**CLAS6 preliminary nDIS data for
Lambda Baryons**

Analysis Team from Mississippi State University:

Prof. Lamiaa El Fassi (Group Leader)

Dr. Latif-ul Kabir

Dr. Taya Chetry

Analysis Contributions from U. Técnica Fed. Santa María:

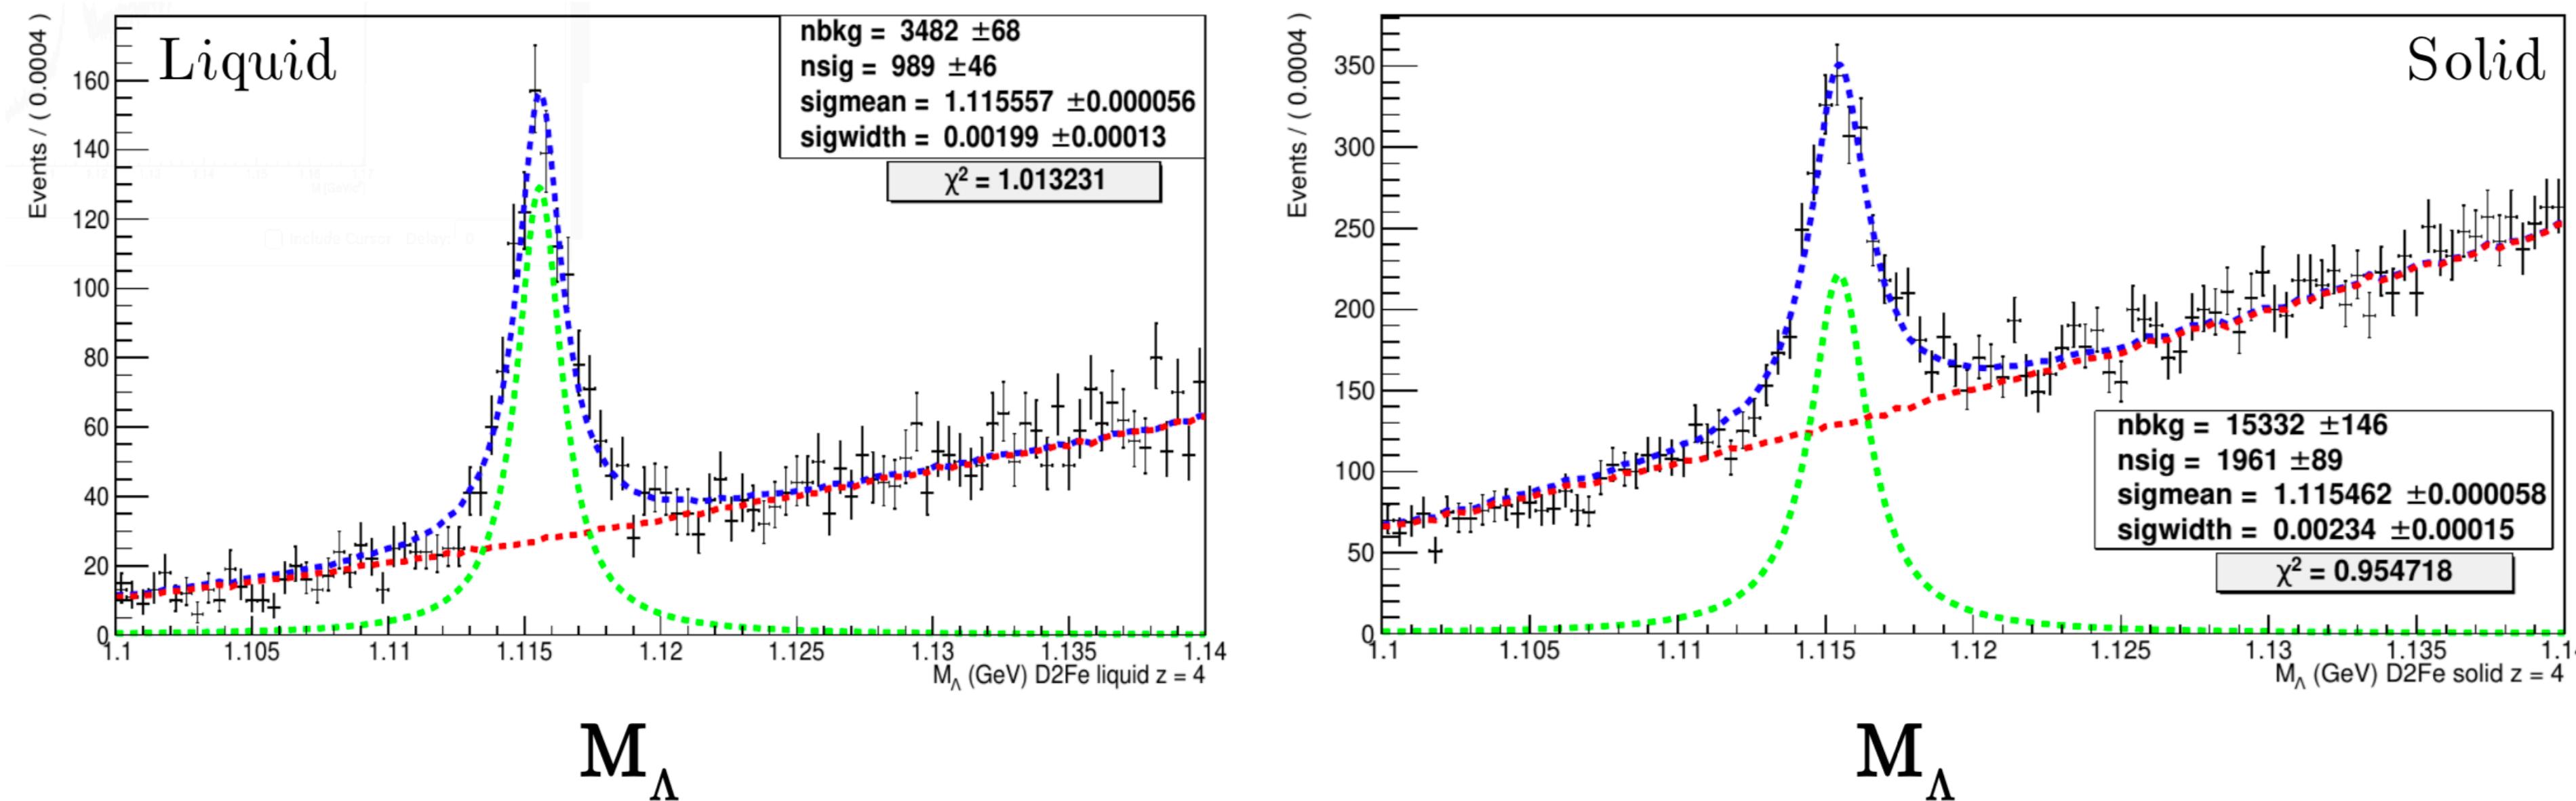

Dr. Ahmed El Alaoui

Some early work performed at ANL.

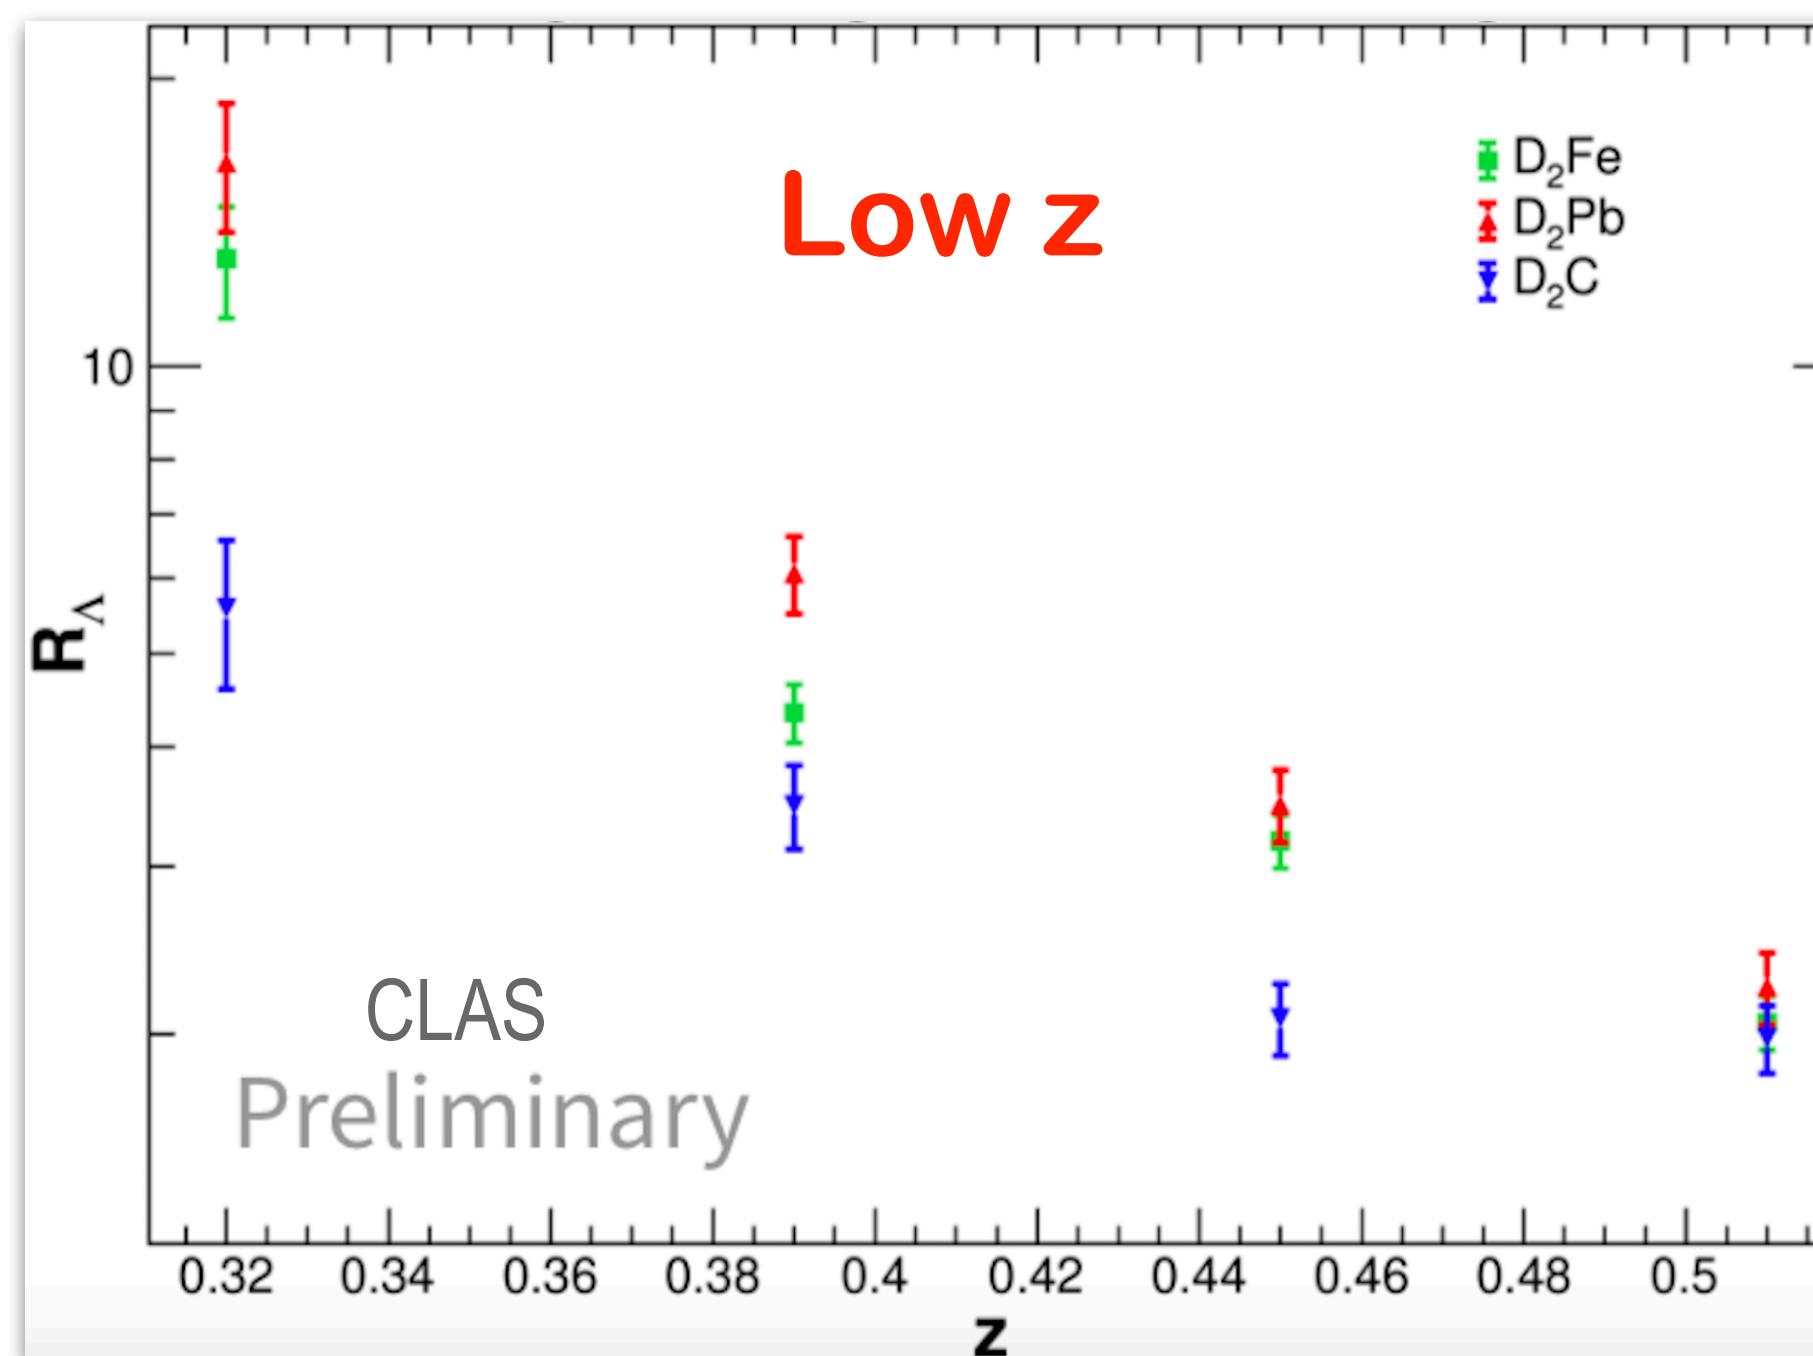

**Uncorrected preliminary results released March 2019 by Nuclear Physics
Working Group of CLAS Collaboration.**

Lambda Baryons are well-identified in π -p channel

$$z = [0.48, 0.54)$$

Backgrounds are under control - three different extraction methods agree

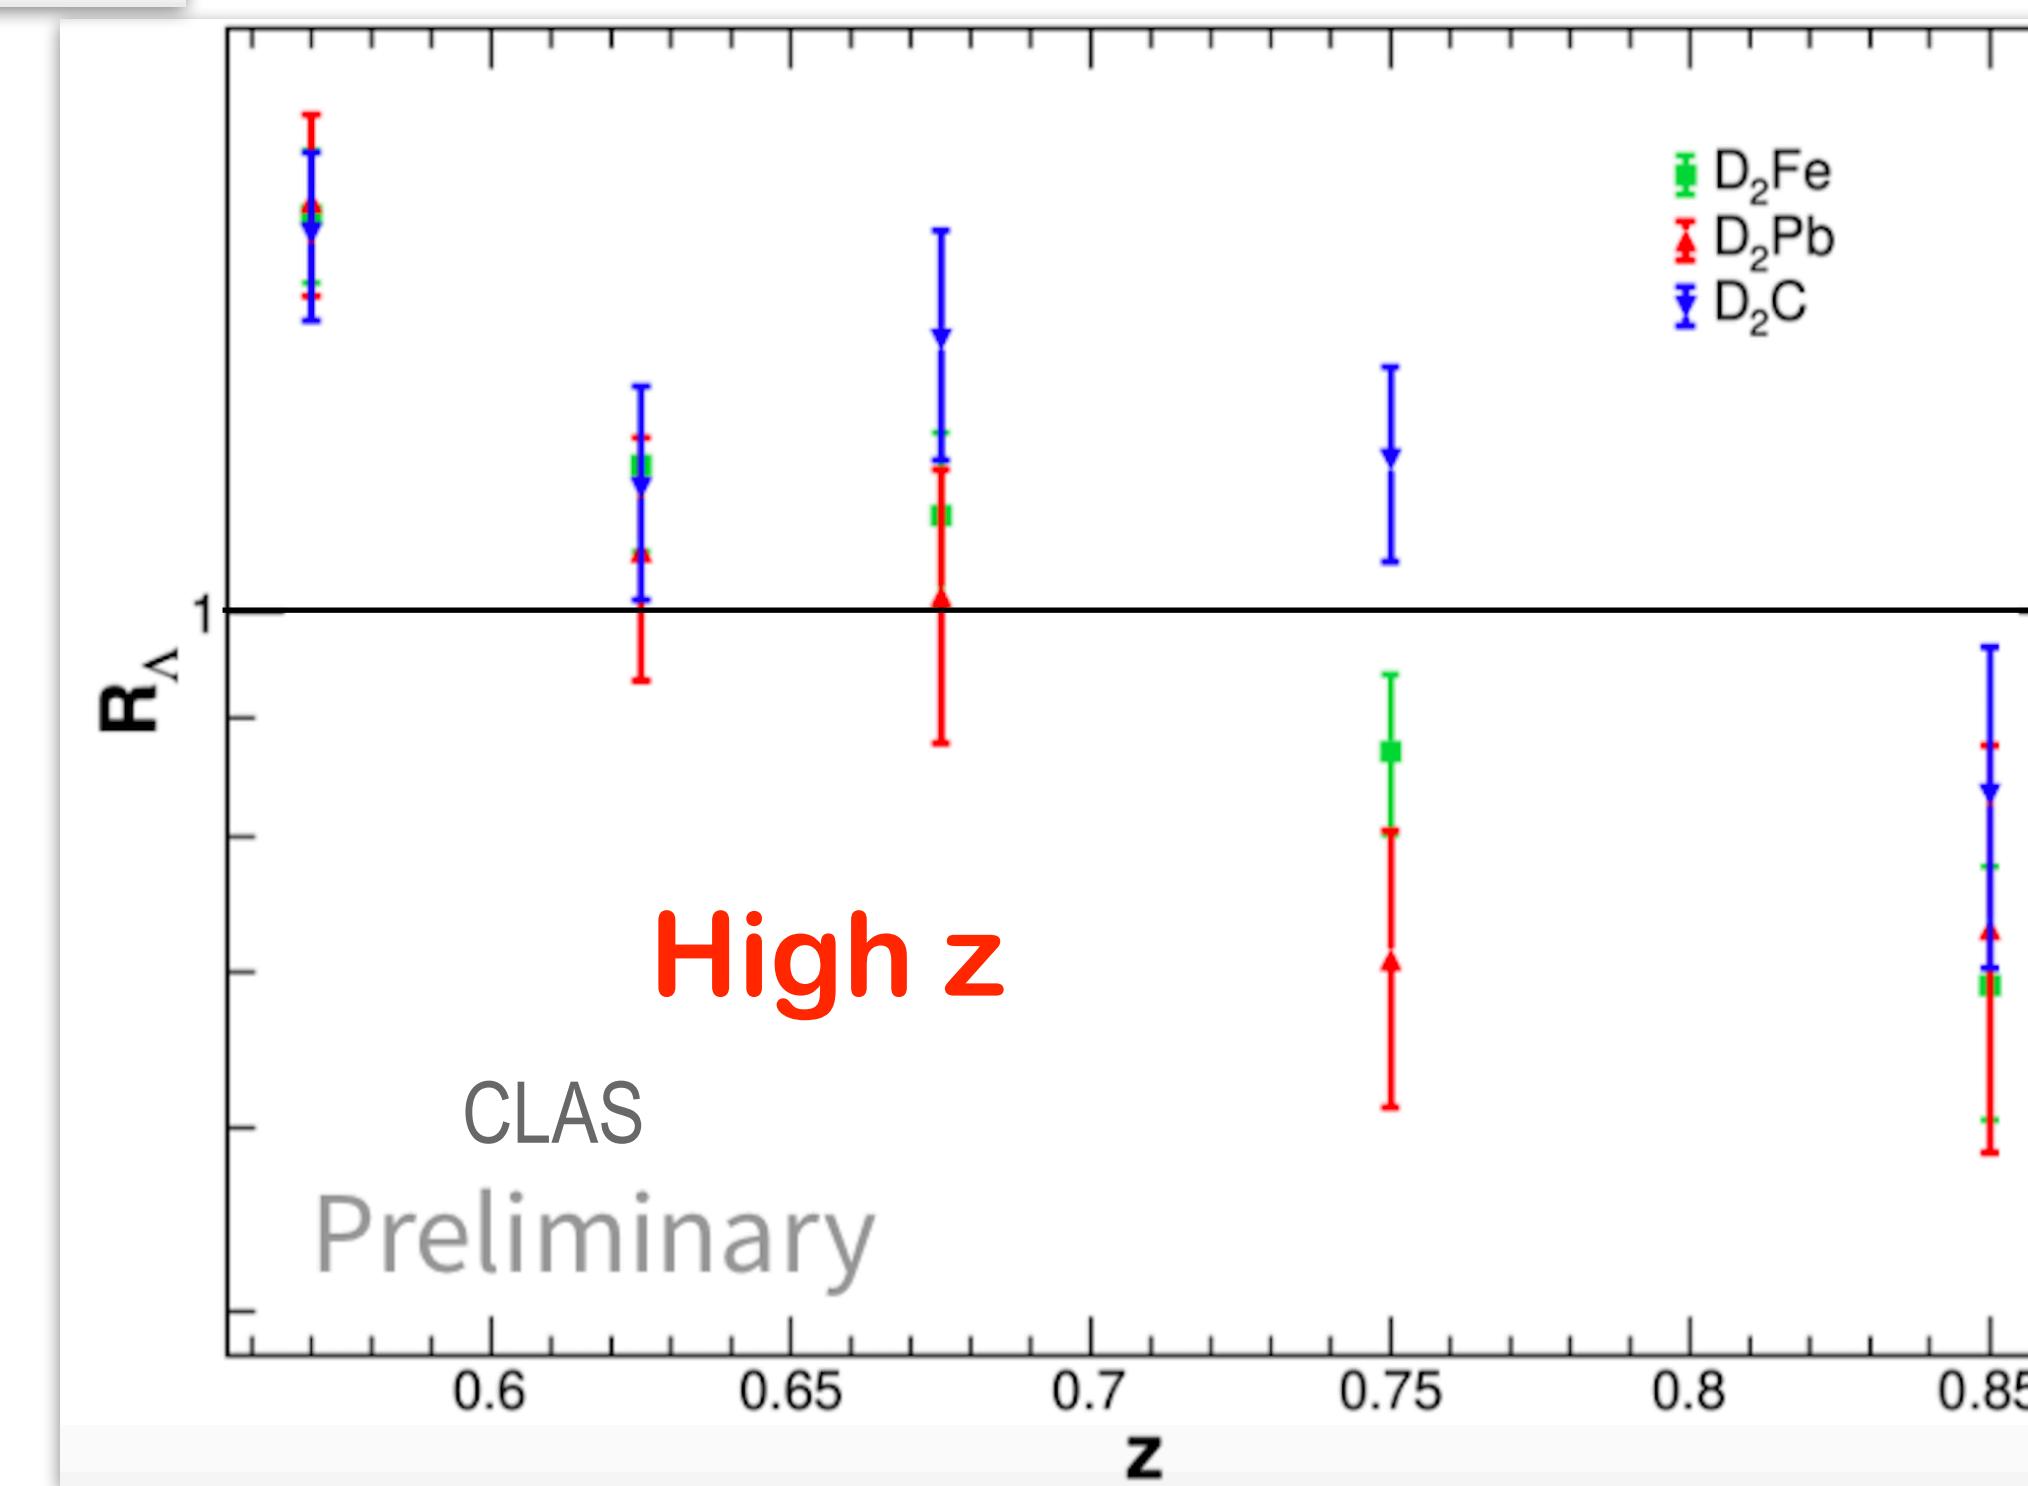

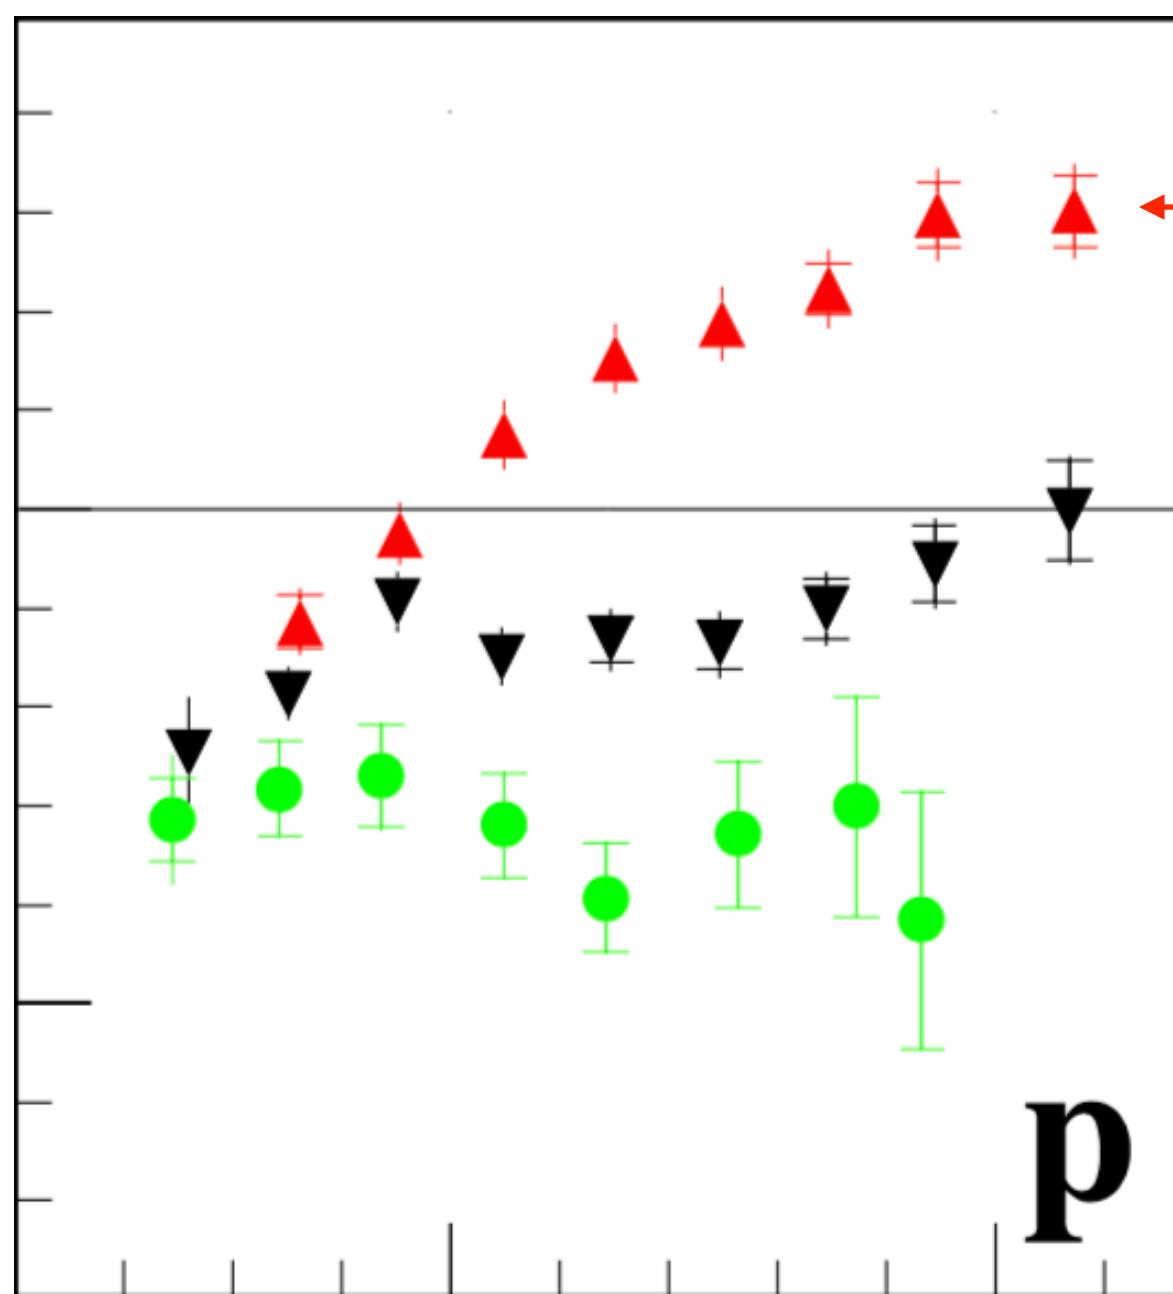

“Pile-up” of events at low z -
huge effect compared to pion
production

Order inverted as expected:
heavy-to-light

At higher z , there is
relatively little
attenuation.

Order as expected:
light-to-heavy

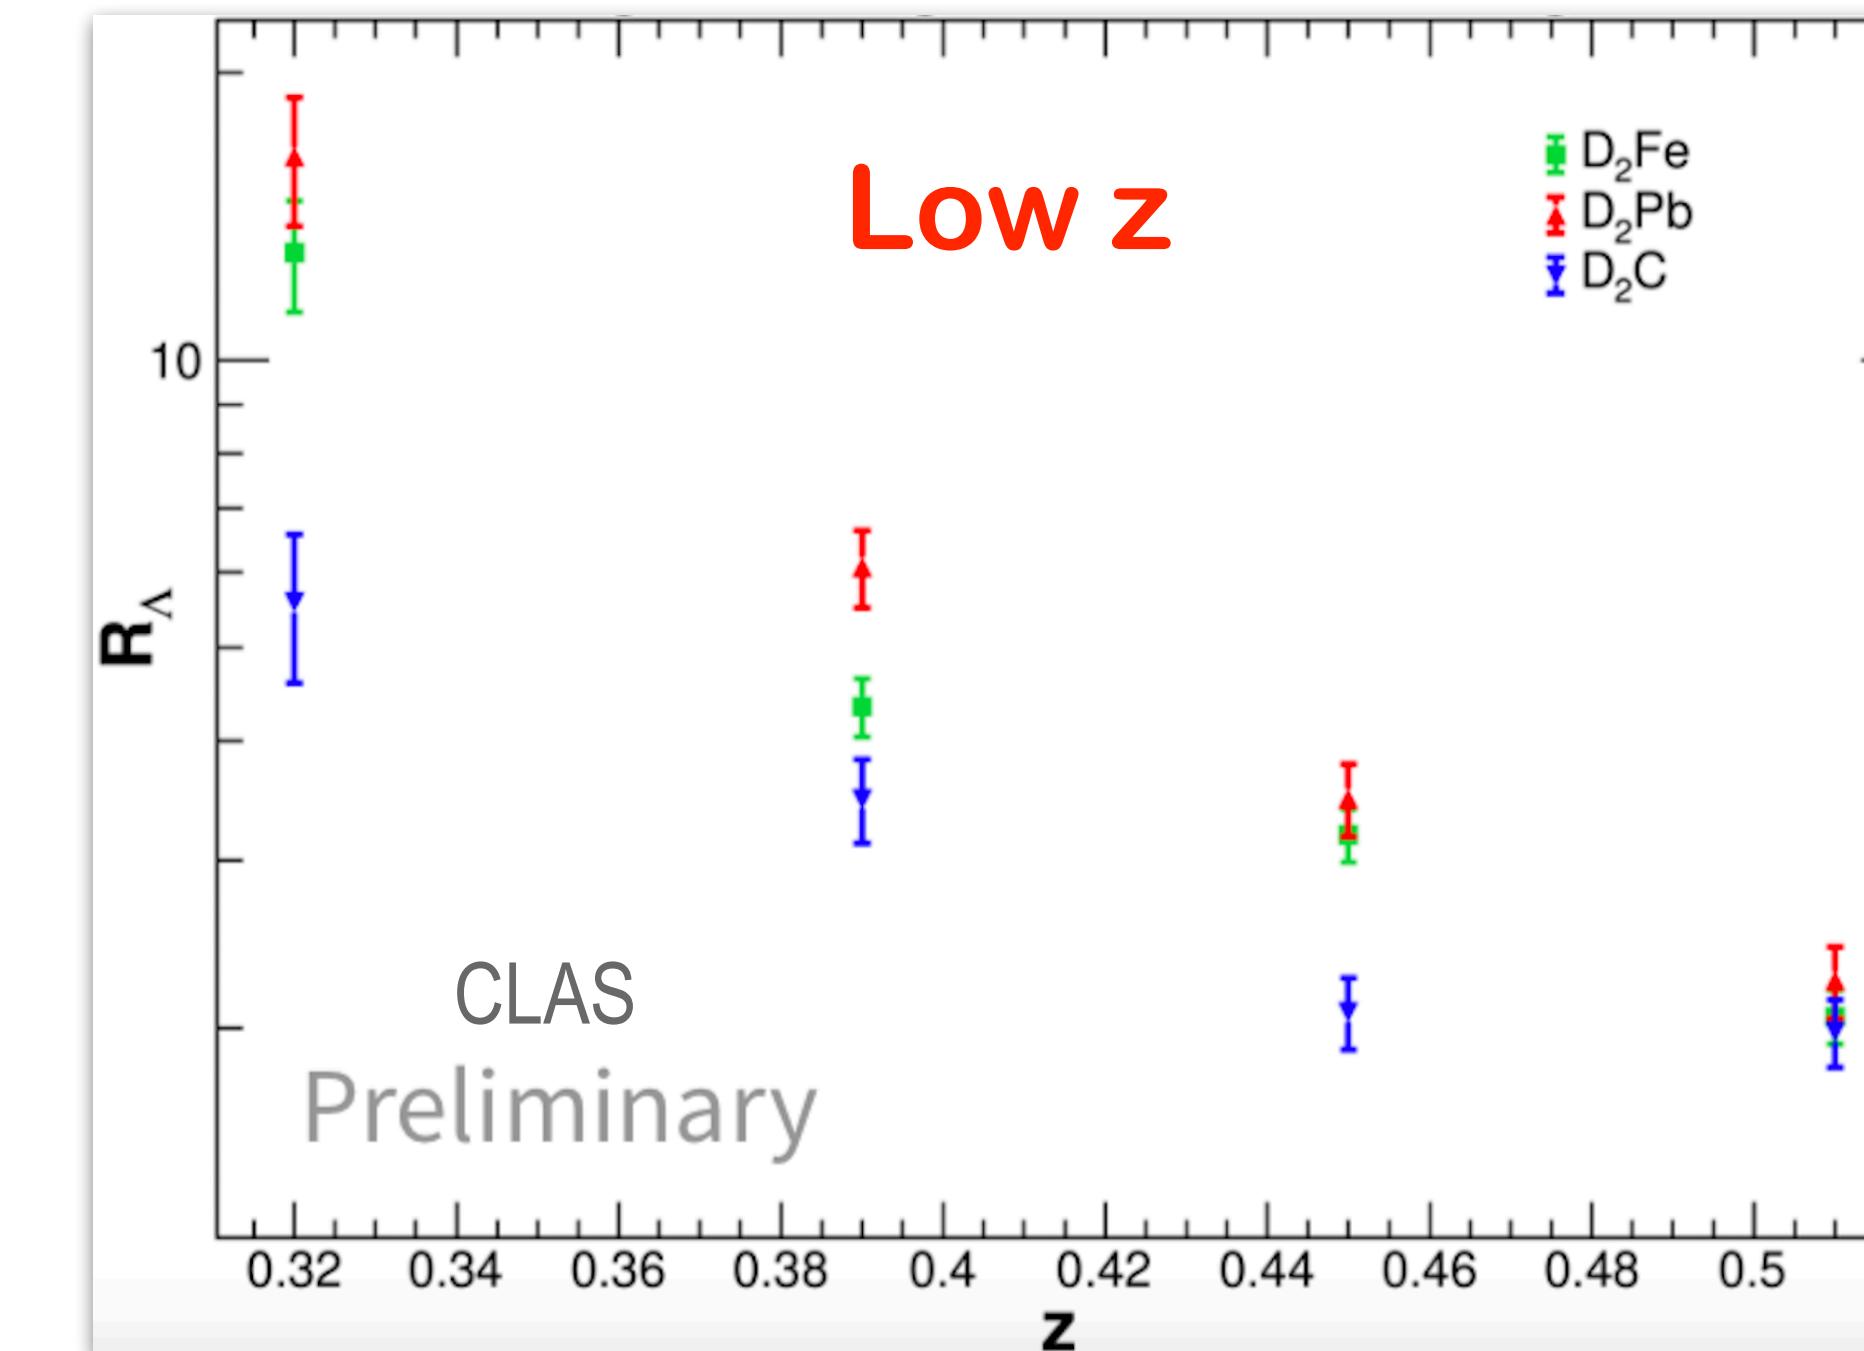

Excess of low-z protons in
HERMES data

Explanation: FSI are
“knocking out protons”??

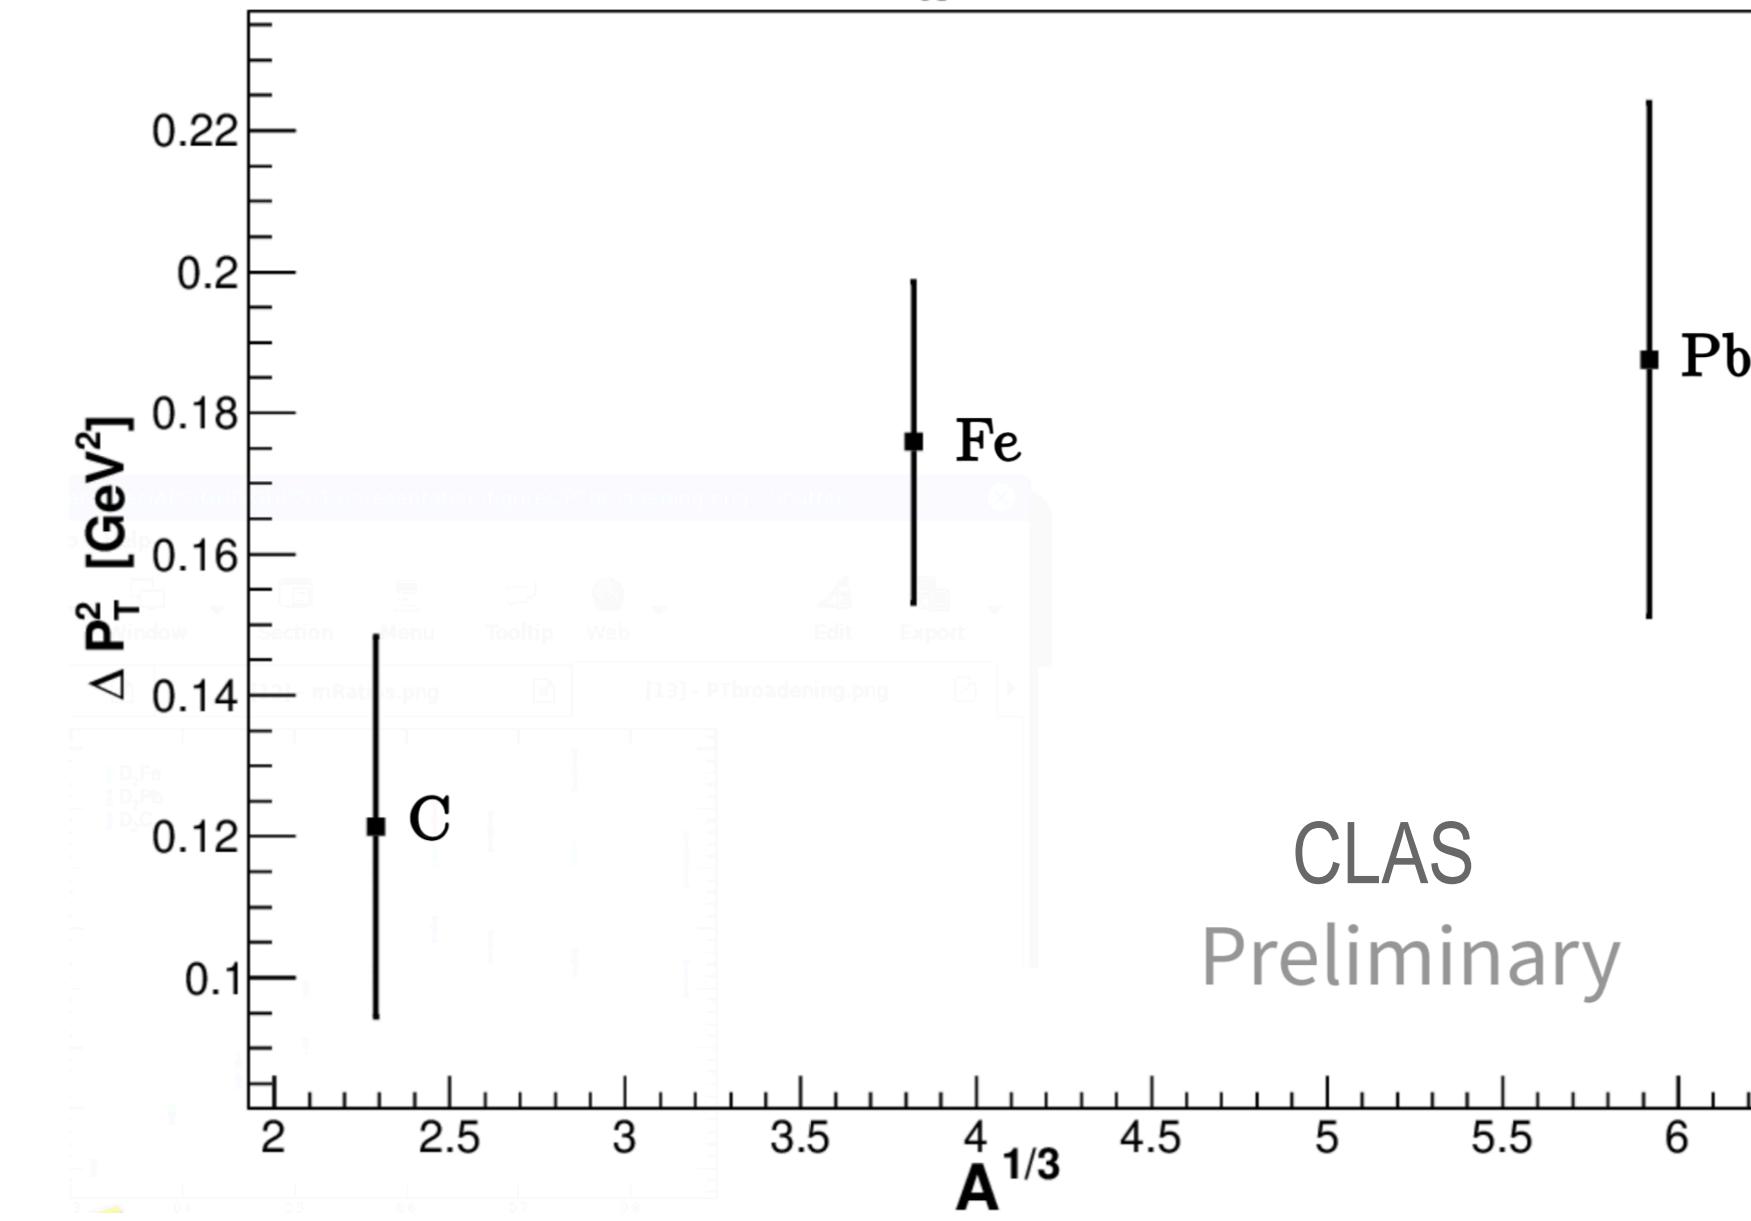

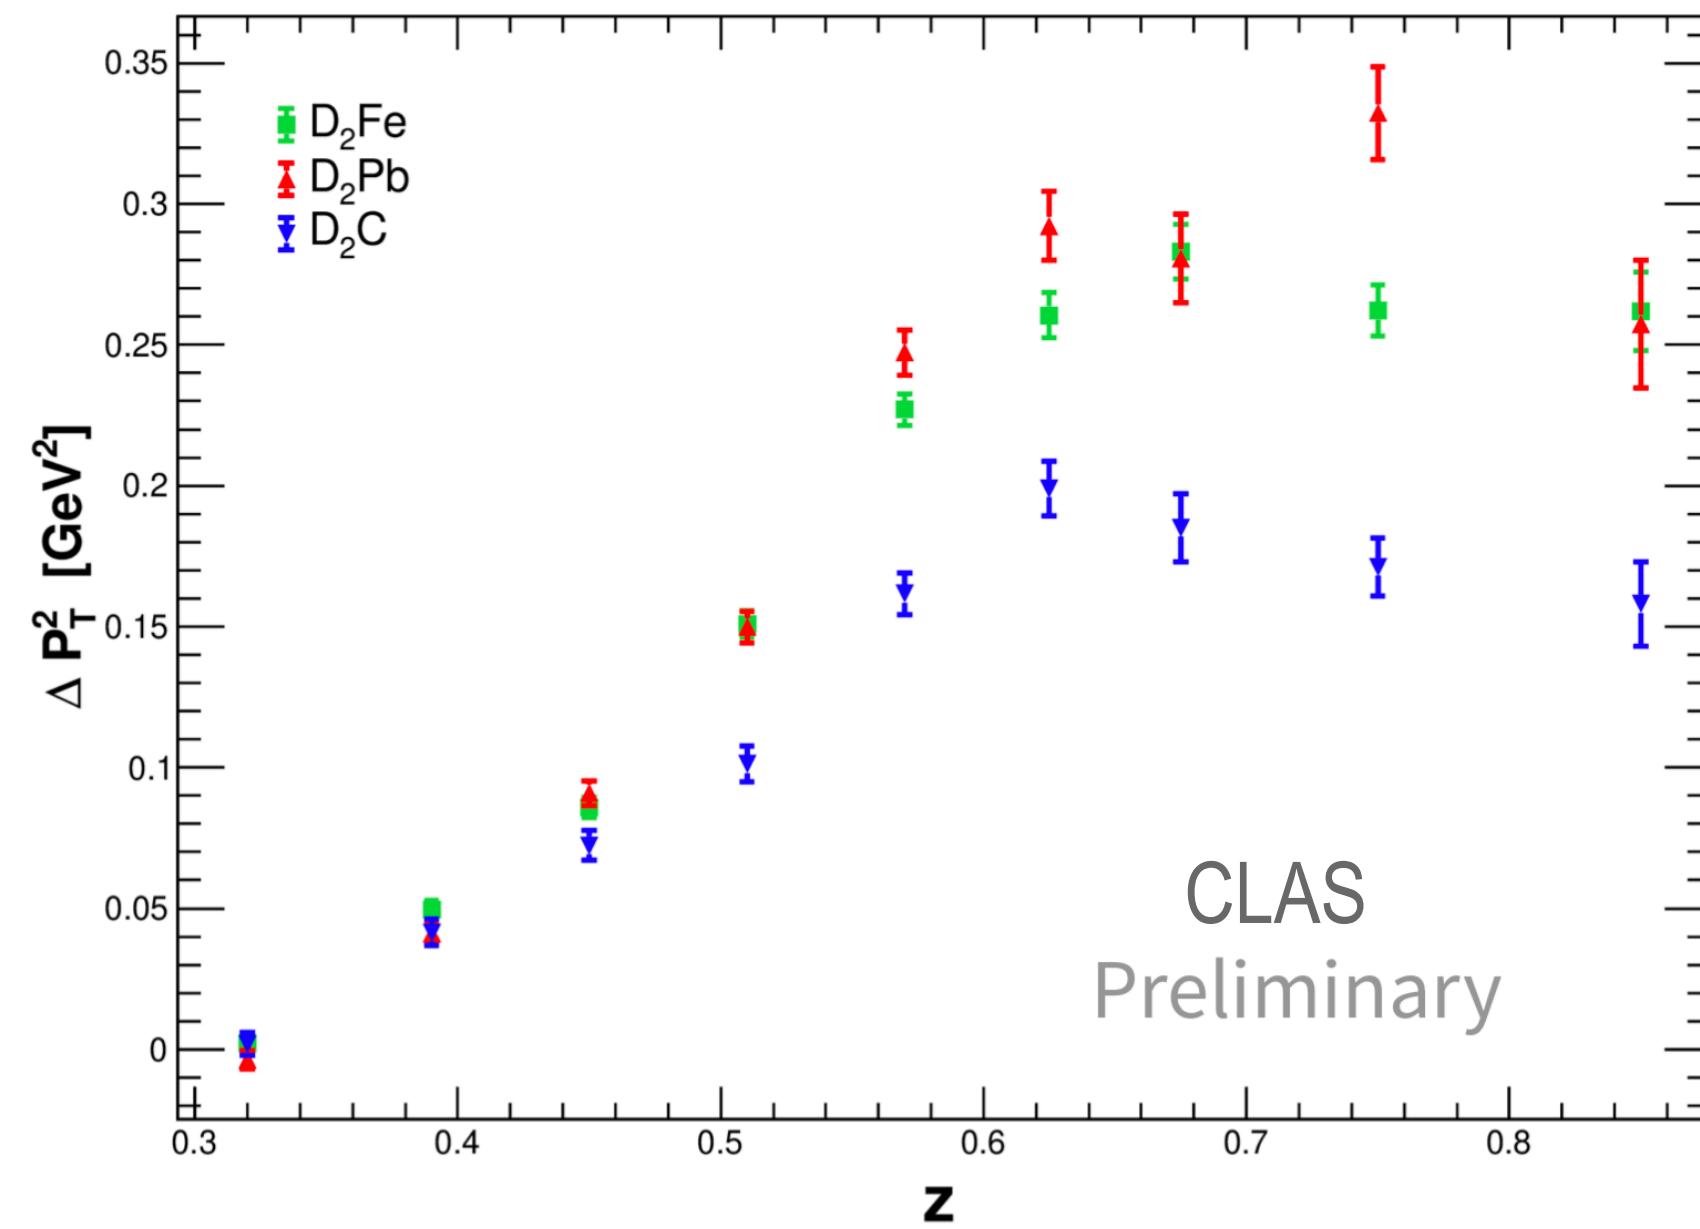

Excess of low-z Lambdas in
CLAS data

Not explained by FSI
“knocking out Lambdas”!!

I have a better explanation

Transverse Momentum Broadening is Large

Maximum is 0.3 GeV^2

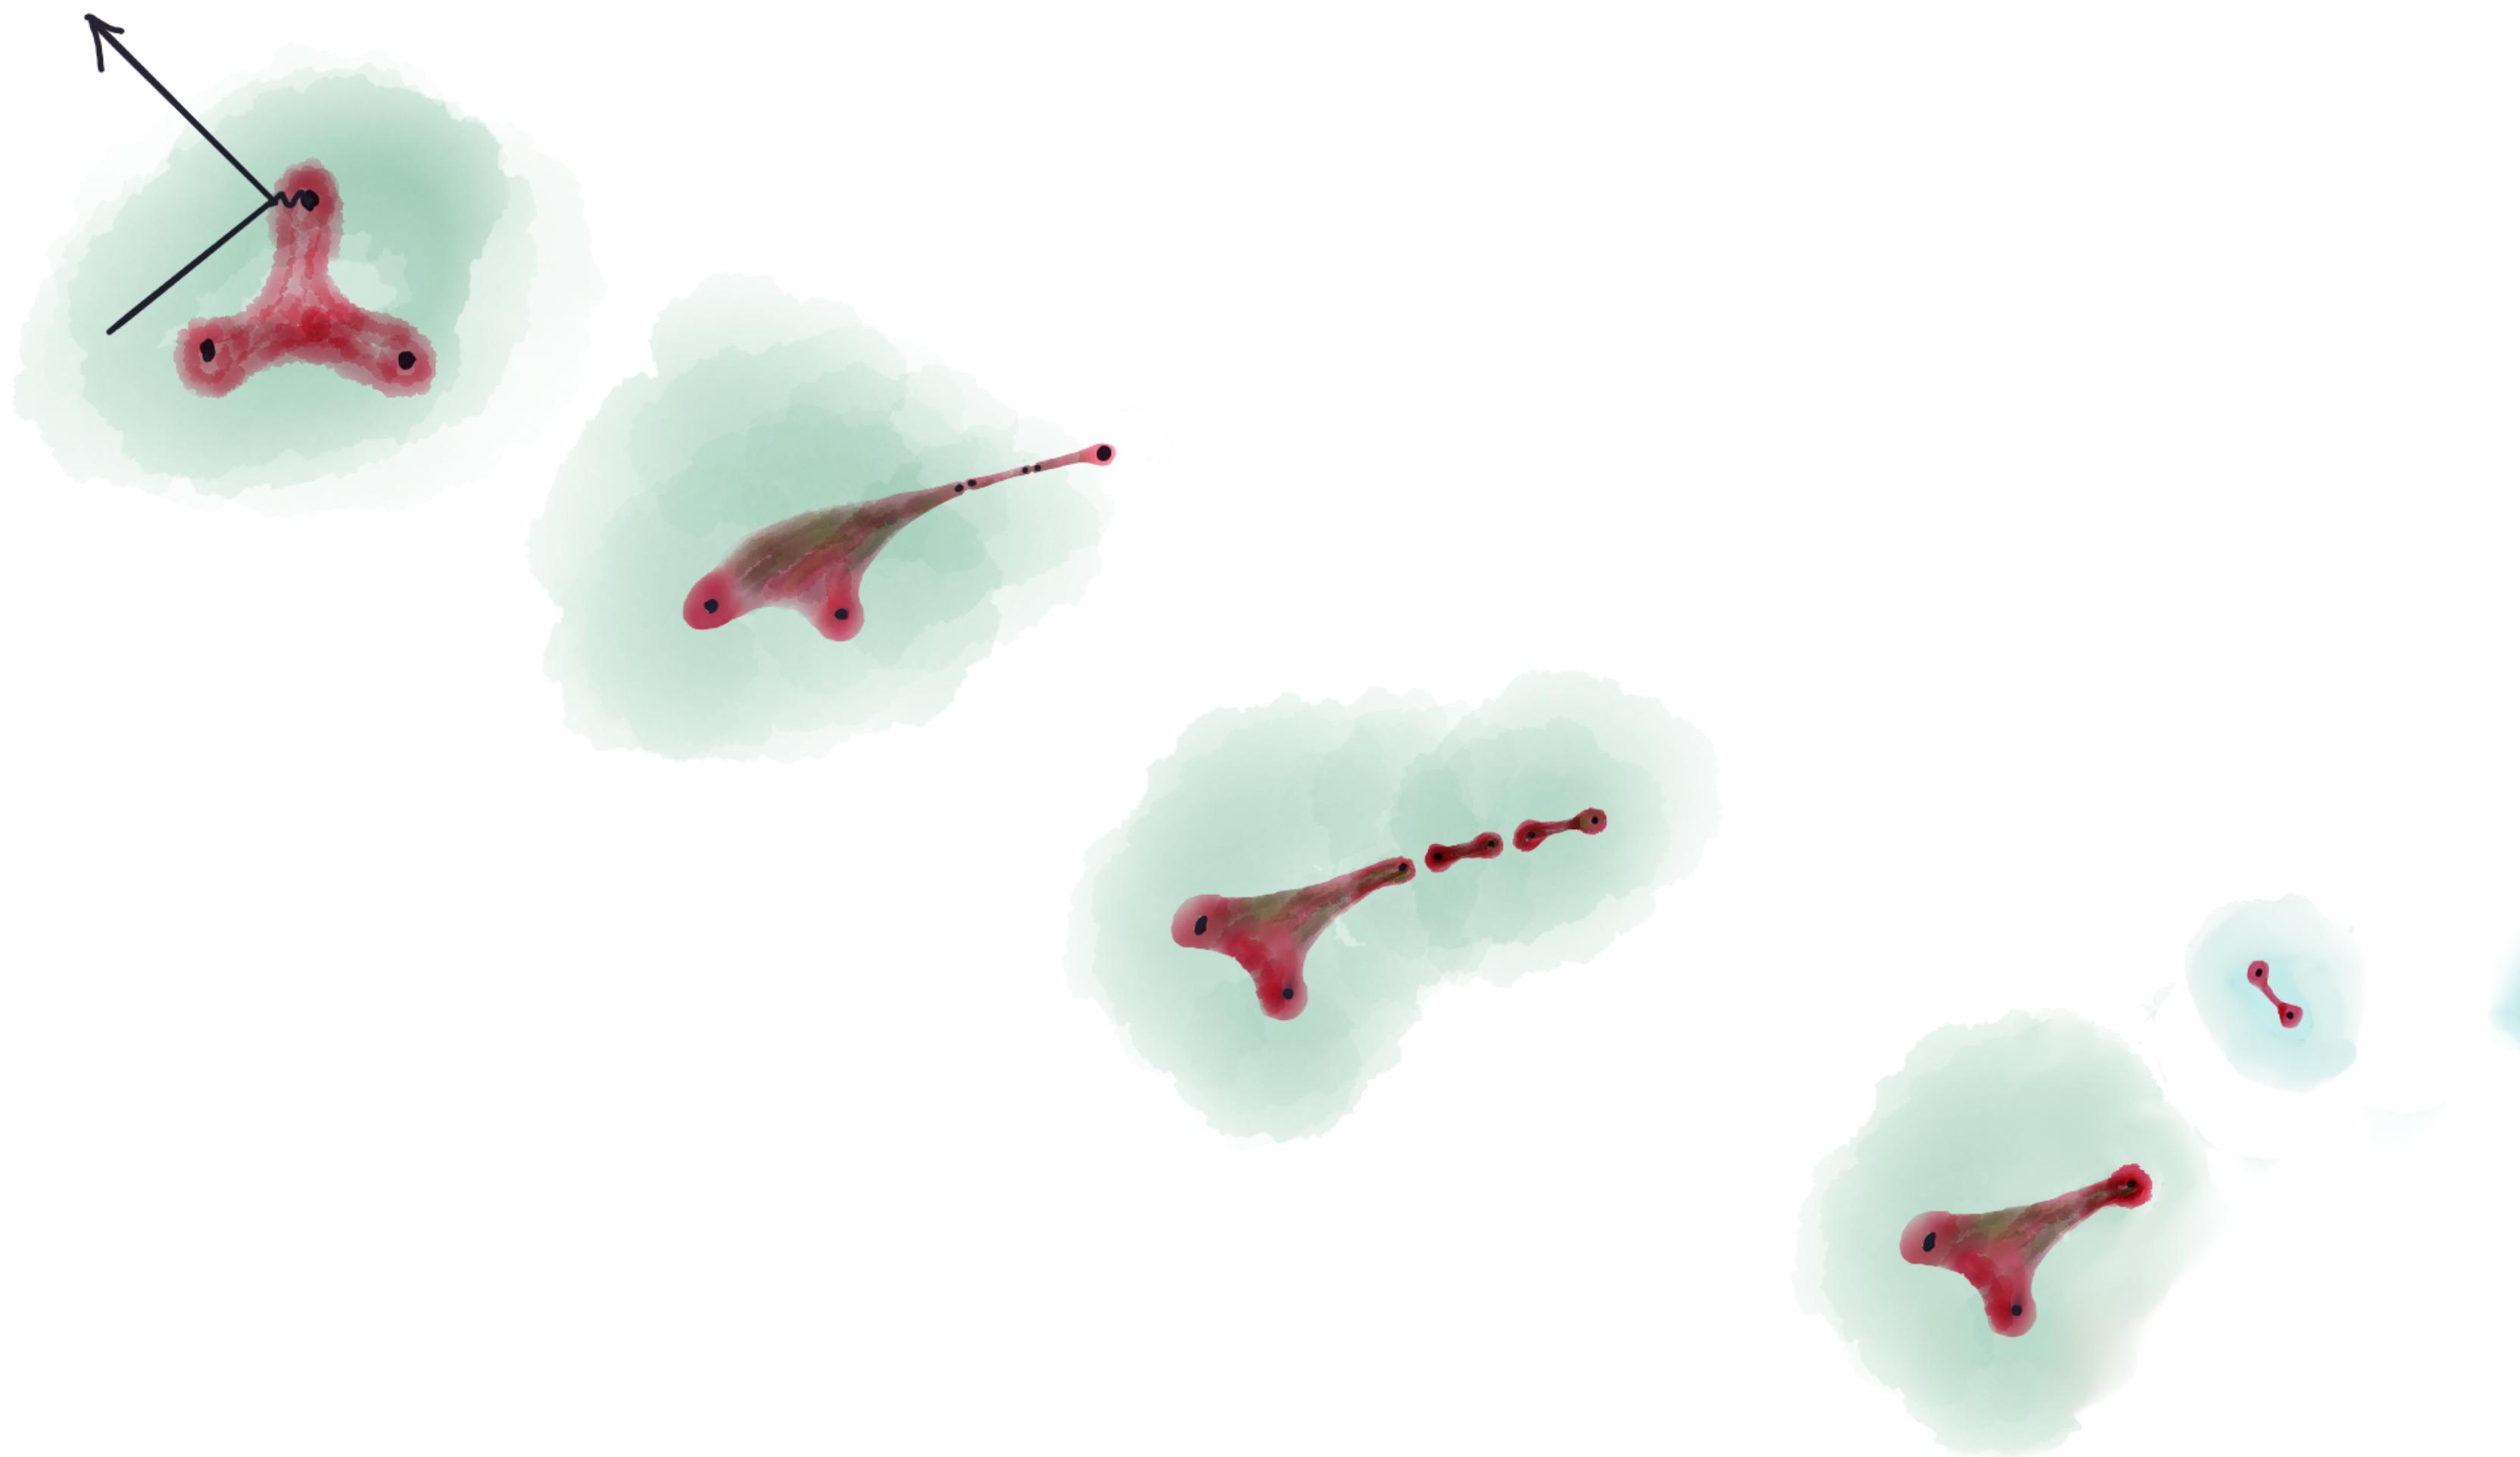

Compare to maximum for pions of 0.03 GeV^2 !

The object passing through the medium is disruptive!
E.g., it is “large” (has an extended color field).

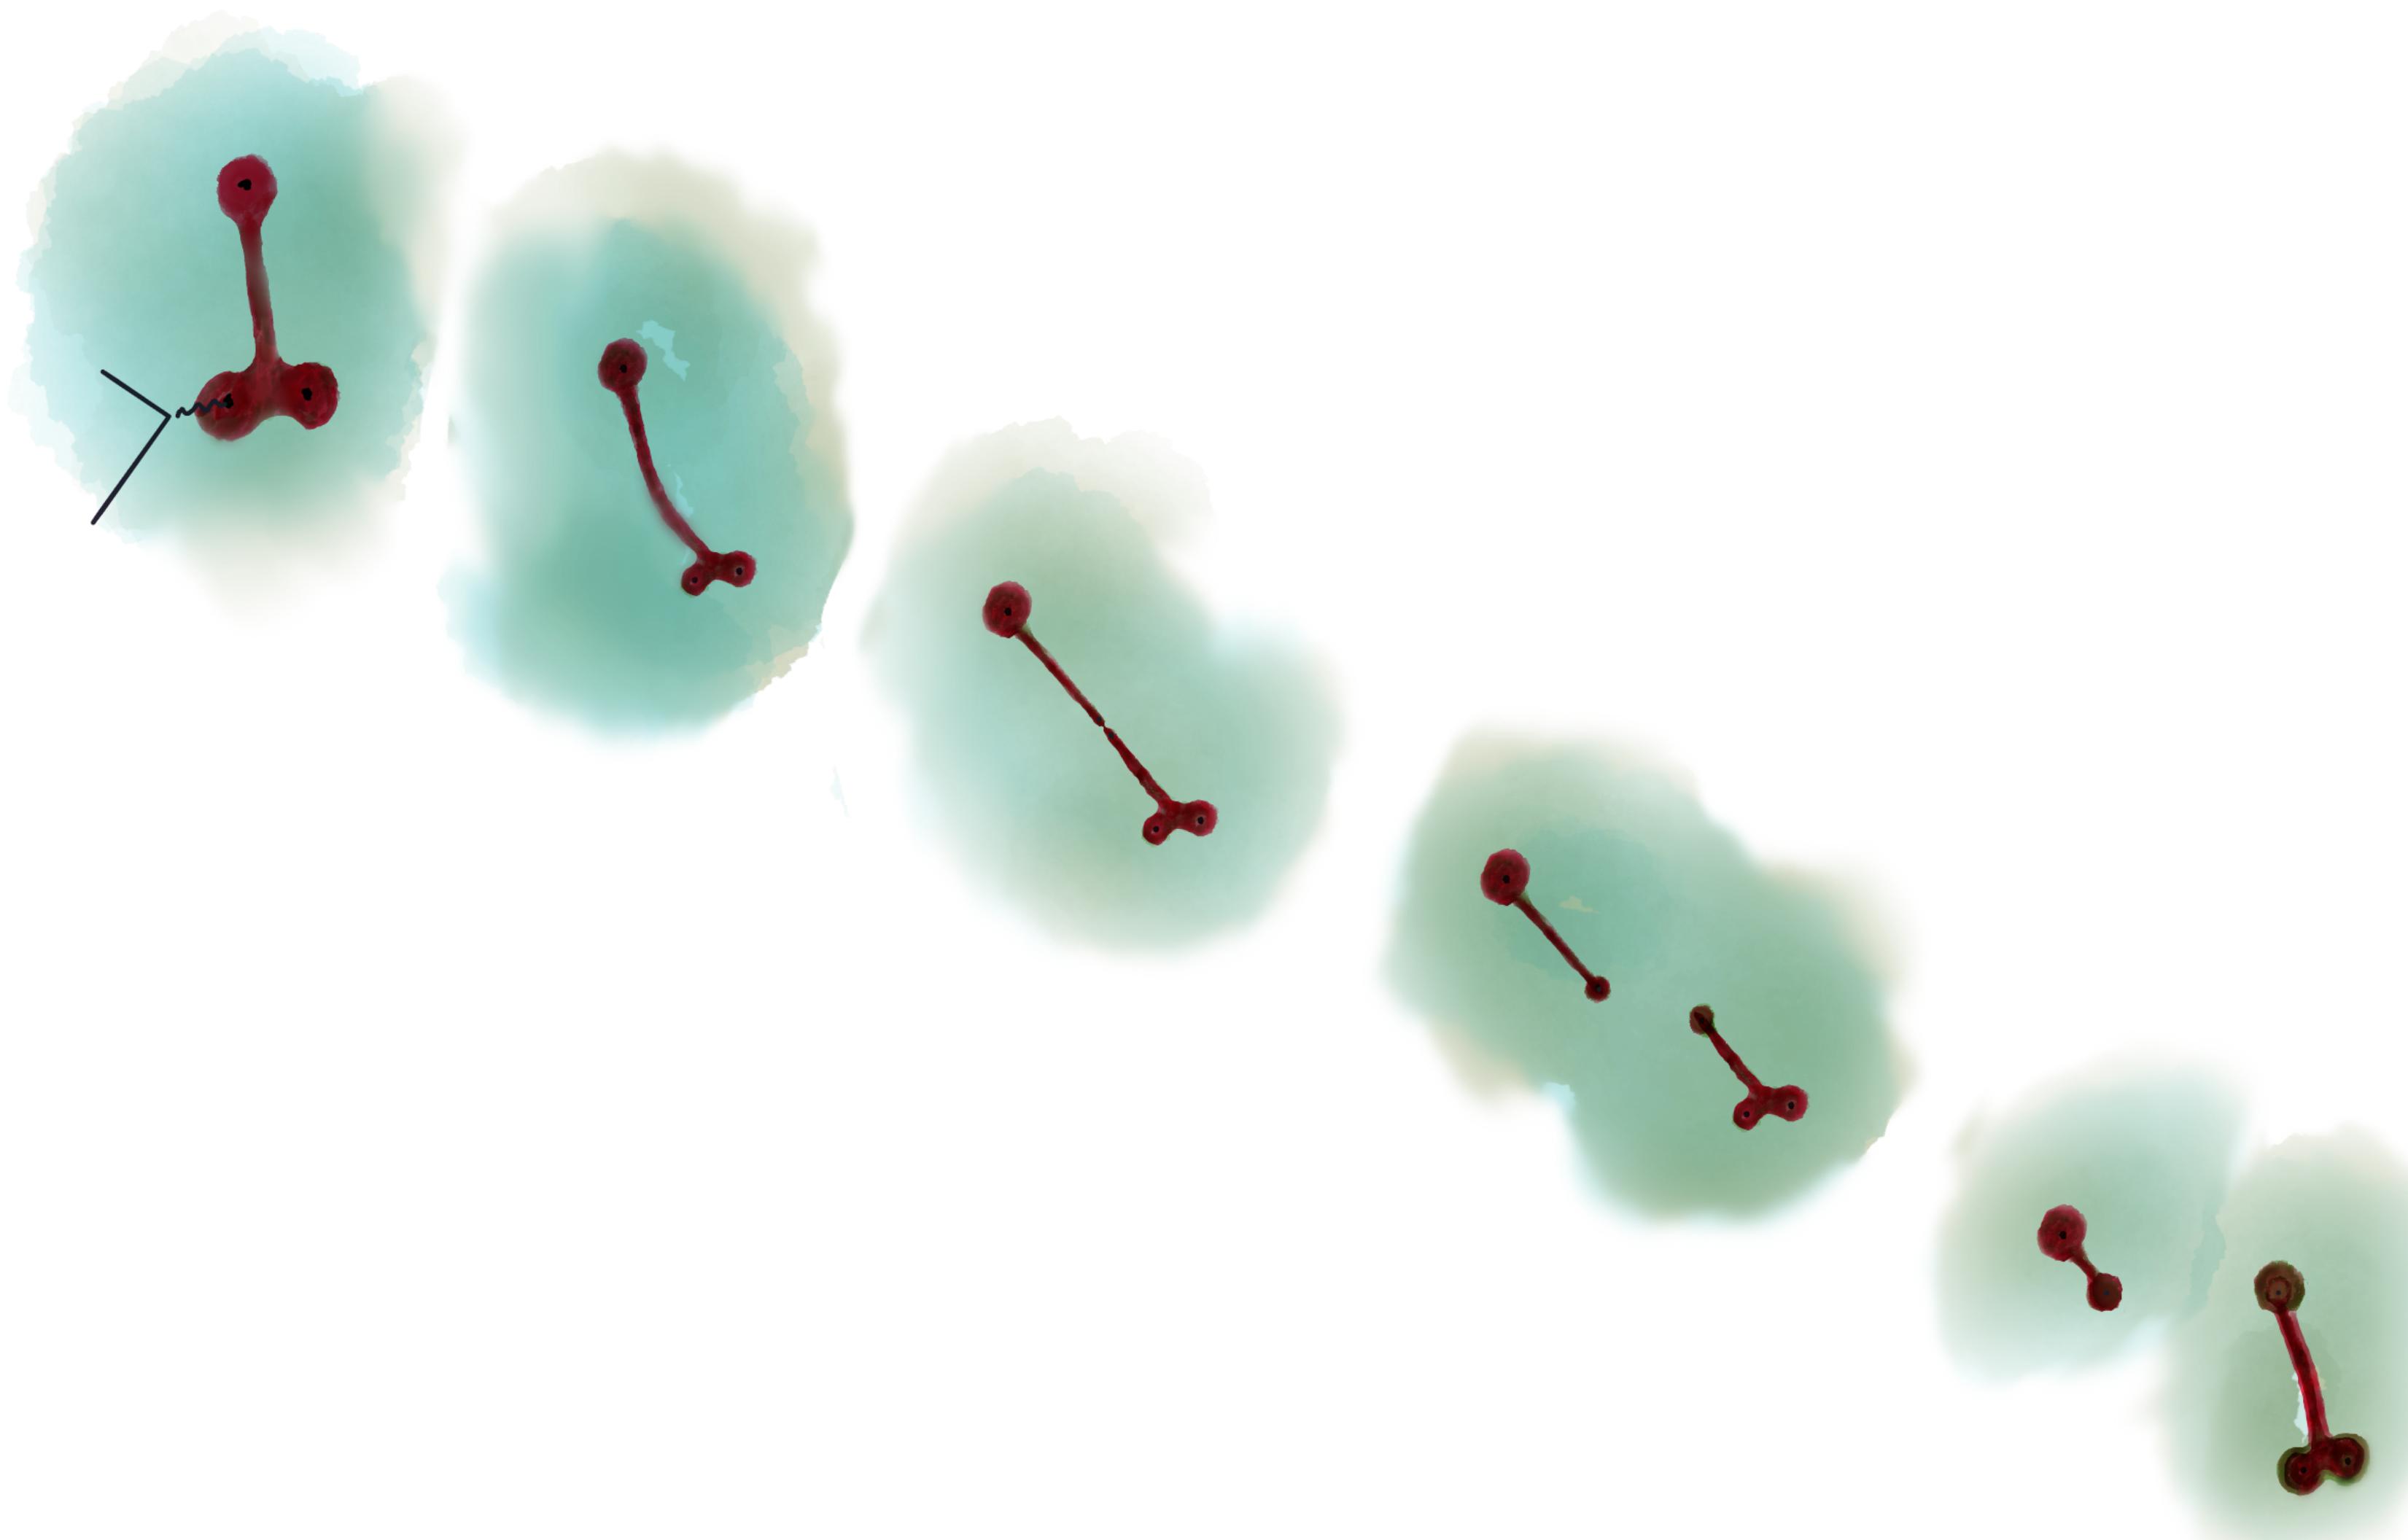

Could it be possible that the virtual photon is absorbed by a diquark?

Let's call this Direct Diquark Scattering (DDS)

Traditional Lund String Model picture of particle production from proton: Single Quark Scattering

Alternative Lund String Model picture of particle production from proton: Direct Diquark Scattering

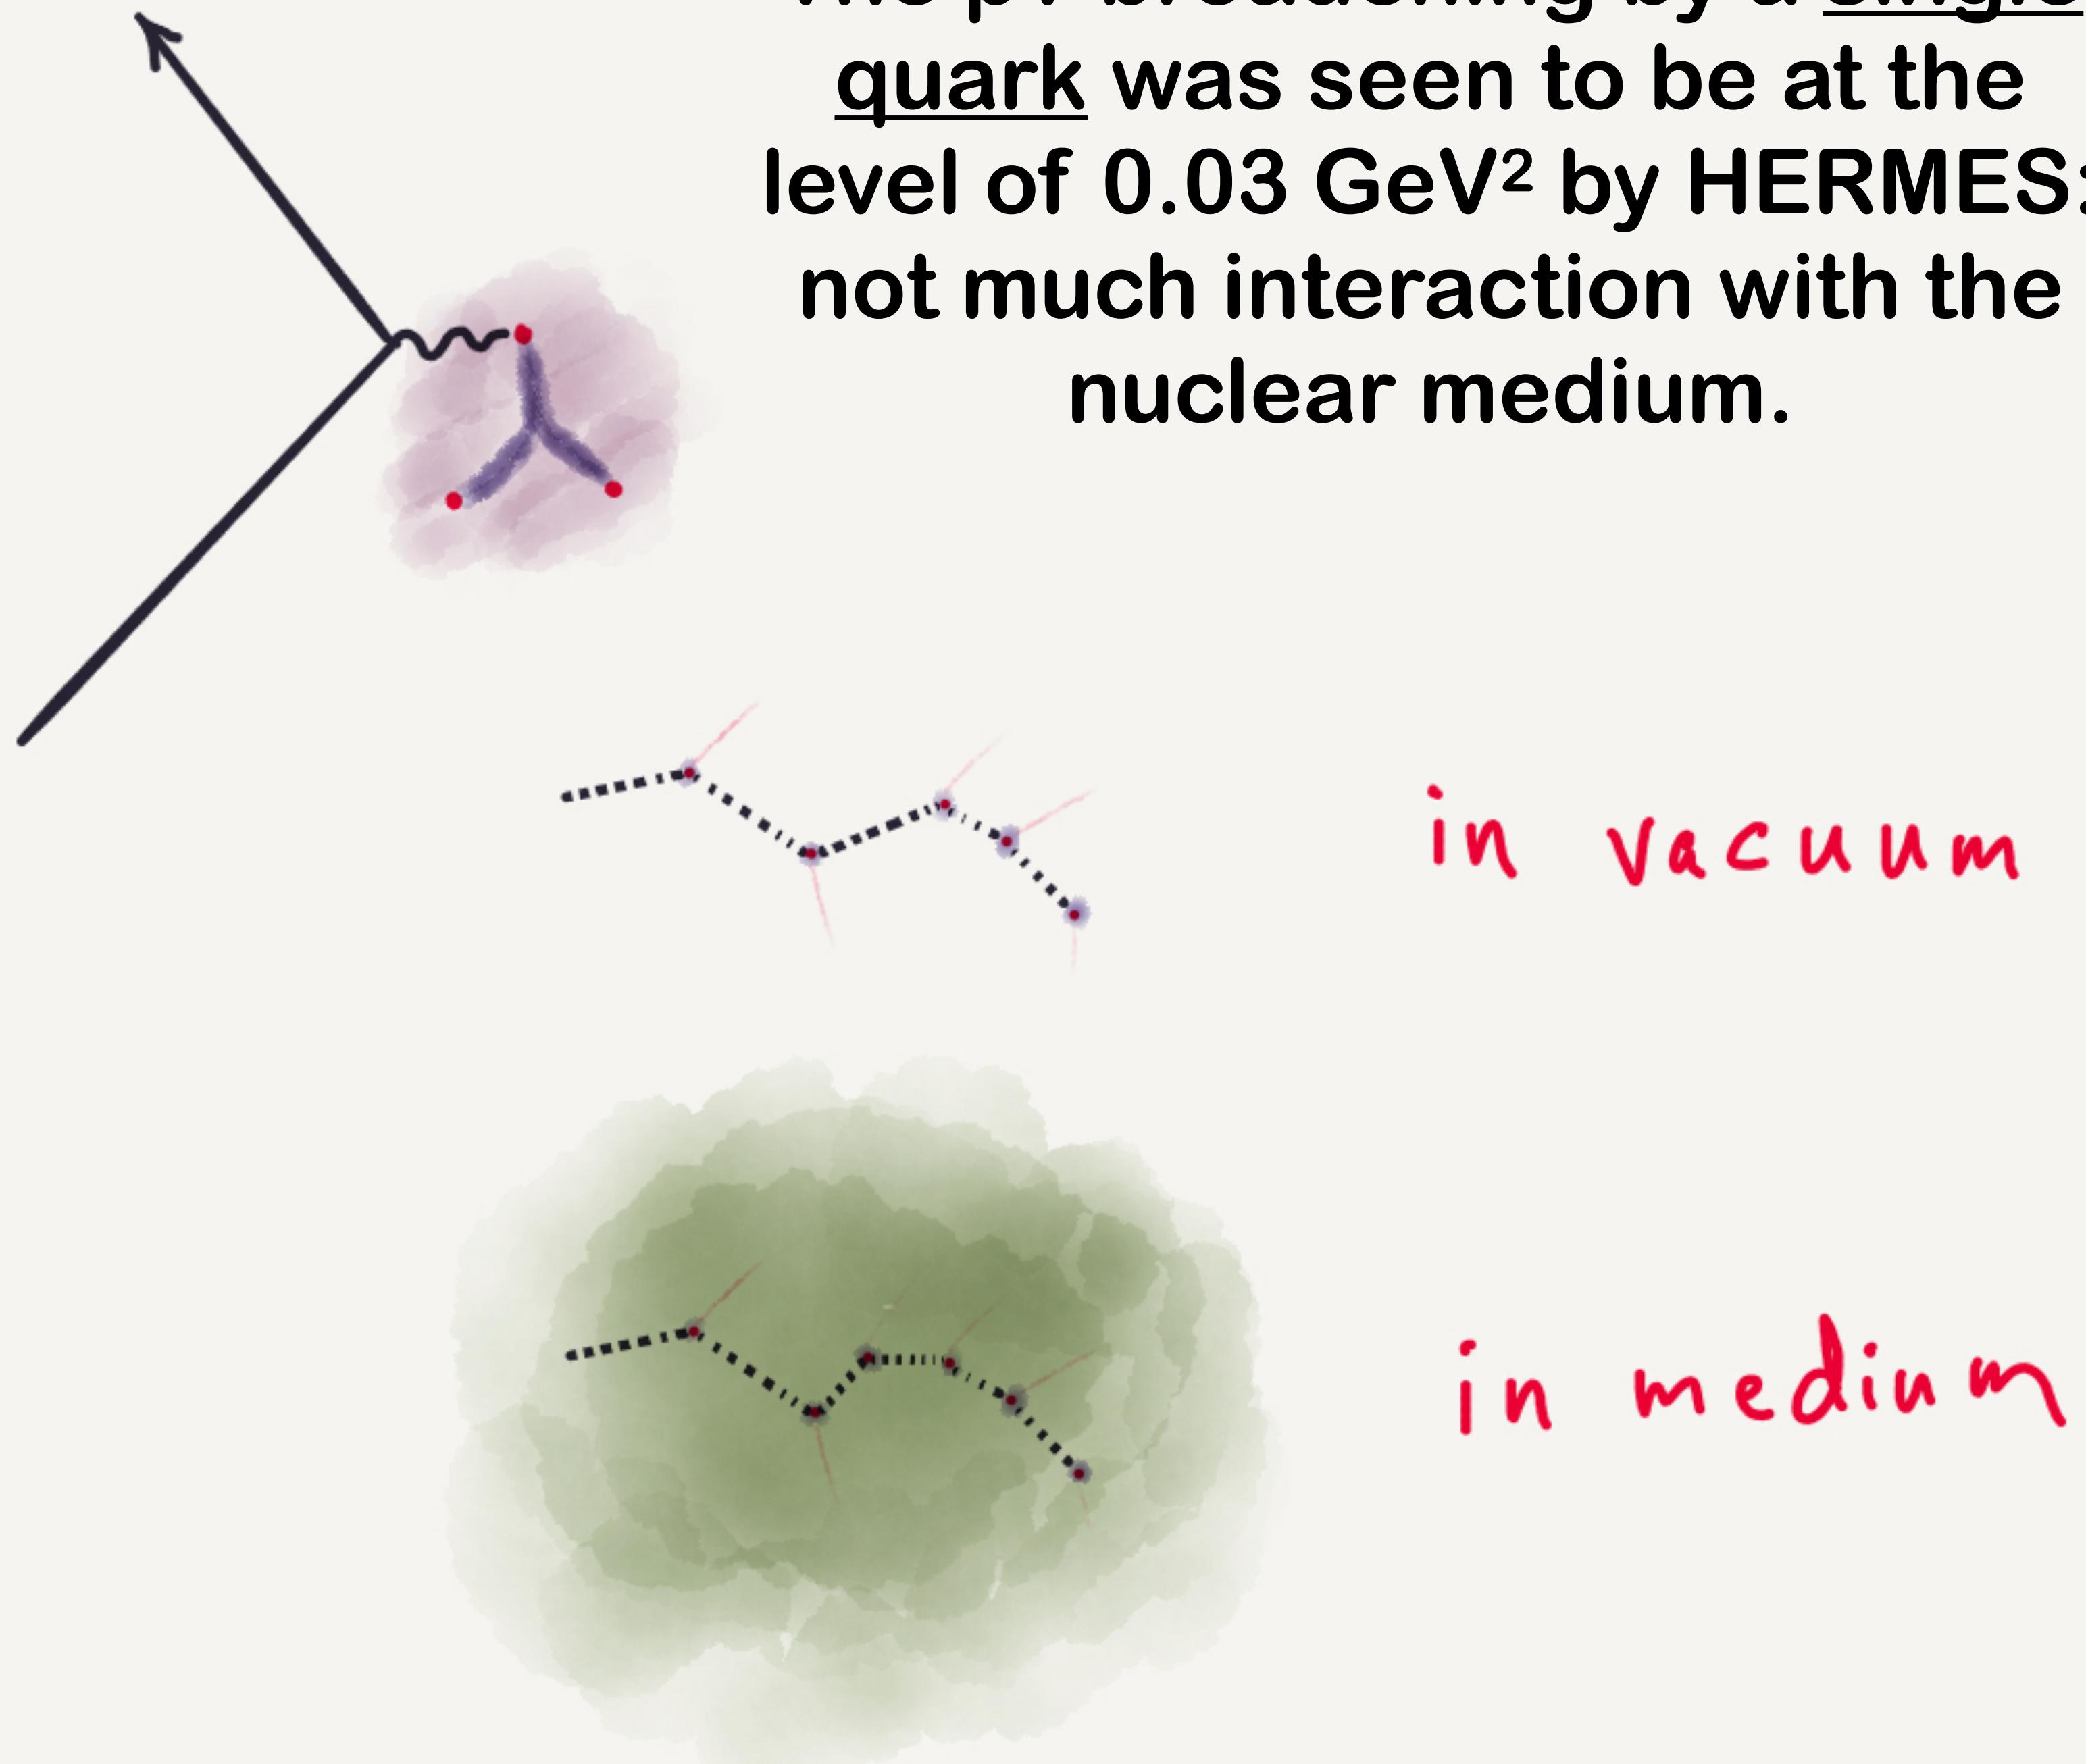

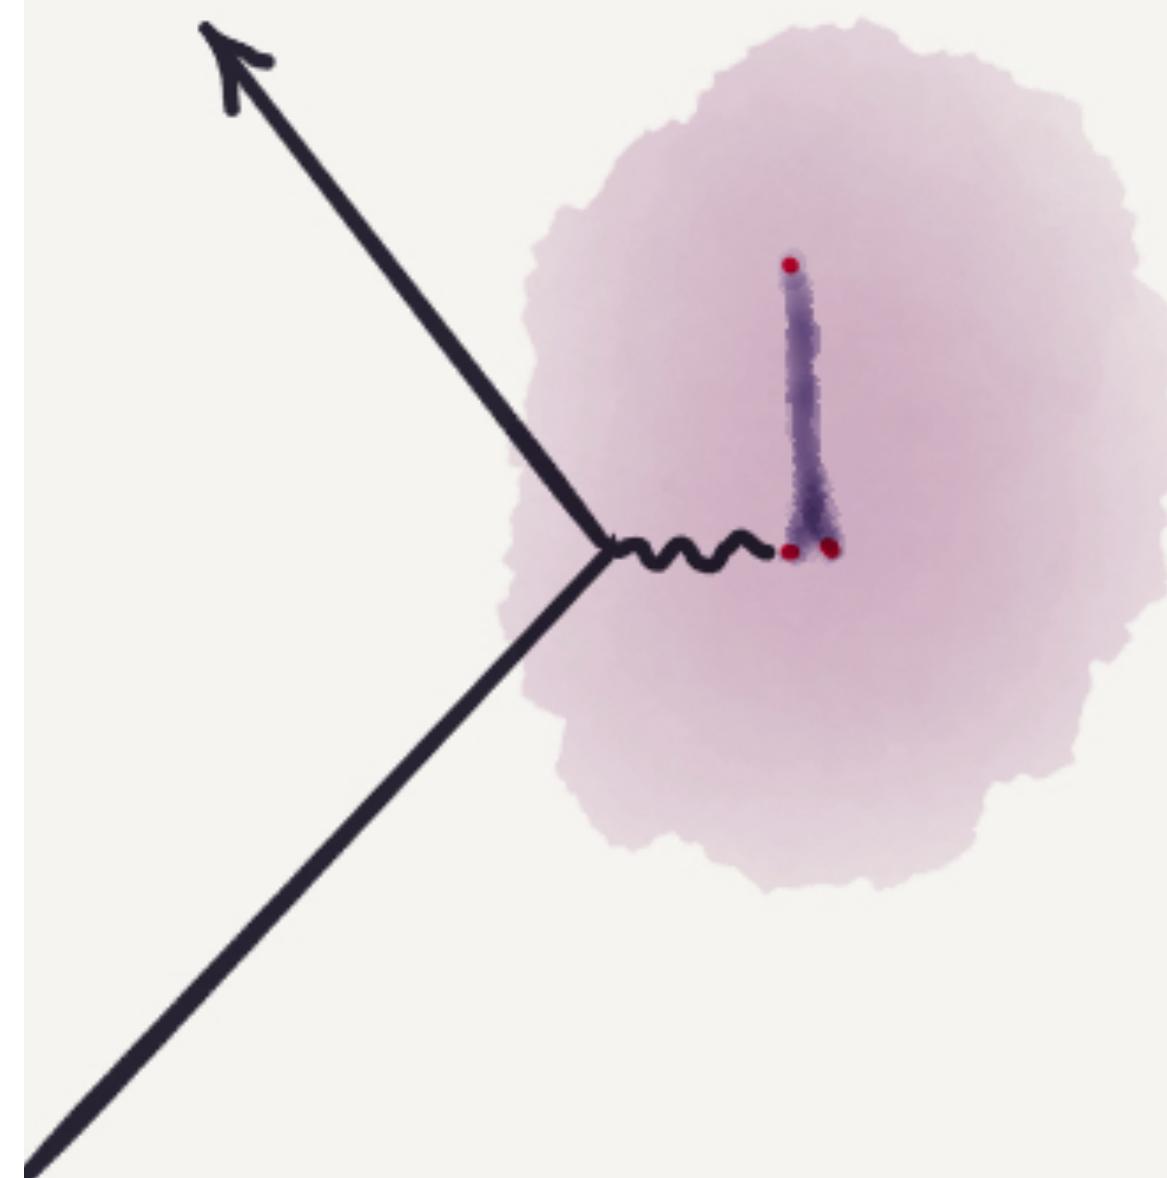

This DDS mechanism makes it **a lot easier to form a proton**. Making a proton in the Lund String Model is famously problematic.

With nDIS baryon production, we will be able to gather a lot of evidence to **test this idea**.

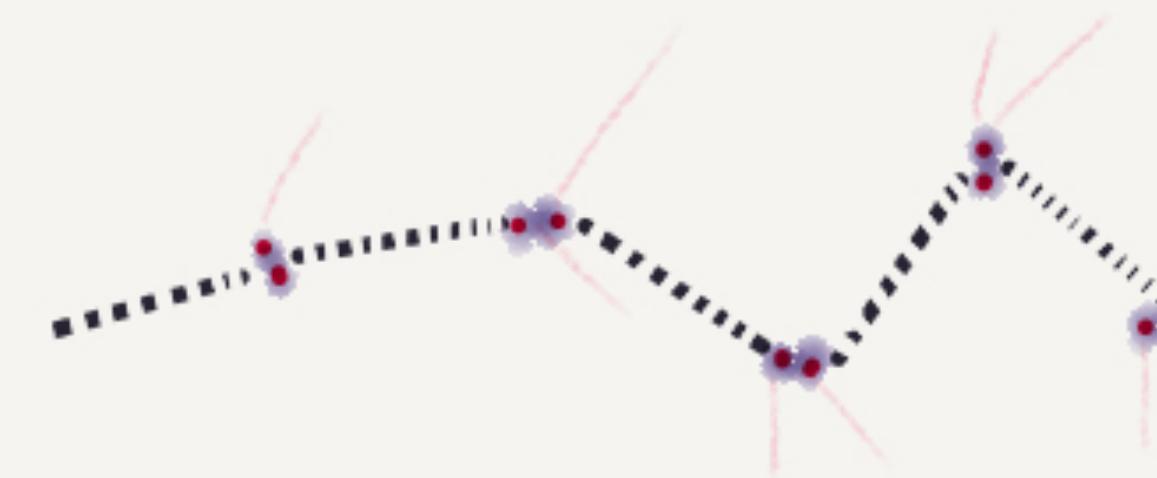

Multiplicity ratio, pT broadening, and correlations between hadrons will provide the evidence.

The pT broadening by a single quark was seen to be at the level of 0.03 GeV^2 by HERMES: not much interaction with the nuclear medium.

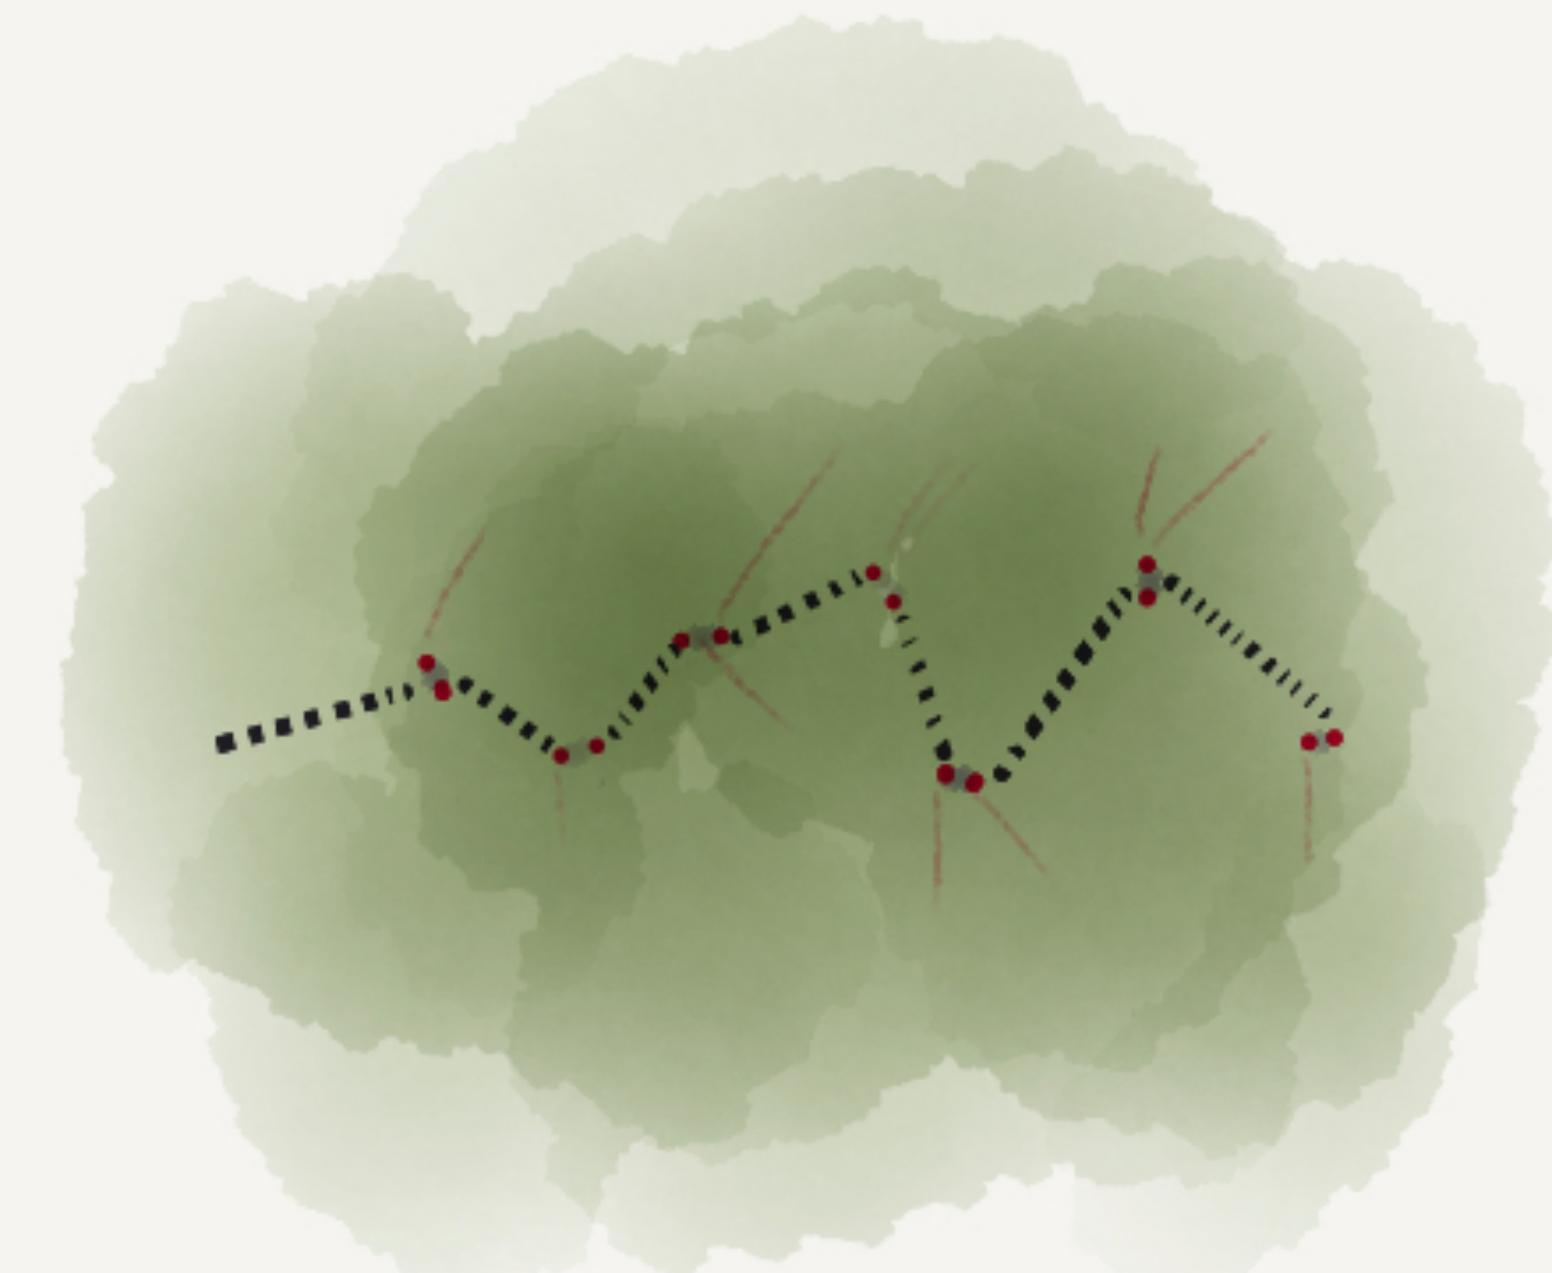

The pT broadening by a diquark
might be much larger: CLAS
lambdas showed up to 0.3 GeV^2 .

in VACUUM

in medium

Further tests of the Direct Diquark Scattering hypothesis with CLAS12 nDIS on baryons

Actively underway with existing 5 GeV data

Conclusions

- A very simple model is able to successfully describe meson production in nDIS. In contrast, baryon data from HERMES and CLAS behave qualitatively differently from mesons.
- The hypothesis is that Direct Diquark Scattering may be the main mechanism for formation of protons and lambdas. Scattering on nuclei yields new insights.
- More theoretical work is needed to determine the feasibility and plausibility of this interpretation.
- The planned and approved CLAS12 Color Propagation program is ideal for testing these ideas: access to production of nine long-lived baryons.

Possible objections to the Direct Diquark Scattering hypothesis

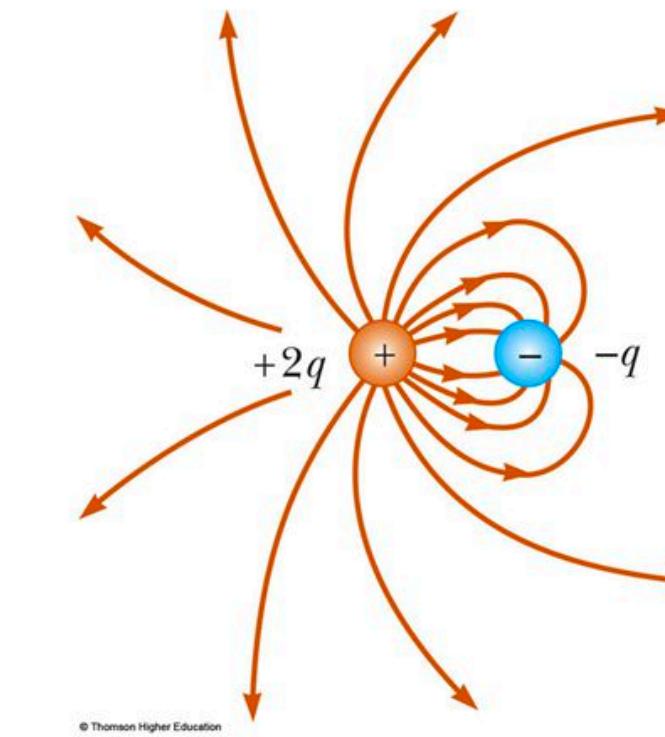

- What about “slingshot” mechanism?
- Hard to reach high z with that. We clearly see large p_T broadening up to high z .

Evidence supporting the Direct Diquark Scattering hypothesis

- pT broadening of the Lambda is huge compared to that of any meson.

Problem: how to hit a diquark?

- Scattering off an electric dipole field?
 - The ud system in close proximity presents an approximate electric dipole
 - This would leave the u and d without a large momentum imbalance
 - Clearly possible in classical picture; not sure how it translates to quantum picture
- Scattering off one quark in close proximity to another quark
 - Followed by gluon exchanges to keep momentum balance from getting too large
 - Smaller phase space, like LHC MPI's.

Alternative hypotheses

- **Quark recombination**
 - Accepted as a mechanism needed to explain aspects of heavy ion collisions, such as J/psi production at low pT.
 - Can explain excess hadron production, in principle.
 - Detailed calculations are needed to see if it can work for lambda, proton, etc.
 - A key feature of producing recombination is elevated temperatures + deconfined system. Unlikely for nDIS.
- **Instant proton/lambda formation**
 - Might help to explain proton results, but not excess of Λ .
