

ML/AI methods for calorimeter simulation

November 9th, 2021

Sofia Vallecorsa - CERN openlab AI and Quantum Research, CERN IT Department

Deep Generative Models

Generative Models learn a probability distribution from the training dataset and produce a new set of examples that belong to the same distribution.

Deep models allow higher levels of **abstractions** and improve **generalization** wrt to **shallow models**

Multiple applications in Simulation, Anomaly Detection, Data manipulation, Data Augmentation

A variety of models:

Generative Adversarial Networks

(Variational) Auto Encoders

Auto-regressive models

Normalizing flows

...

ABSTRACT: We provide a bridge between generative modeling in the Machine Learning community and simulated physical processes in High Energy Particle Physics by applying a novel Generative Adversarial Network (GAN) architecture to the production of *jet images* – 2D representations of energy depositions from particles interacting with a calorimeter. We propose a simple architecture, the Location-Aware Generative Adversarial Network, that learns to produce realistic radiation patterns from simulated high energy particle collisions. The pixel intensities of GAN-generated images faithfully span over many orders of magnitude and exhibit the desired low-dimensional physical properties (*i.e.*, jet mass, *n*-subjettiness, etc.). We shed light on limitations, and provide a novel empirical validation of image quality and validity of GAN-produced simulations of the natural world. This work provides a base for further explorations of GANs for use in faster simulation in High Energy Particle Physics.

The precise modeling of subatomic particle interactions and propagation through matter is paramount for the advancement of nuclear and particle physics searches and precision measurements. The most computationally expensive step in the simulation pipeline of a typical experiment at the Large Hadron Collider (LHC) is the detailed modeling of the full complexity of physics processes that govern the motion and evolution of particle showers inside calorimeters. We introduce CALOGAN, a new fast simulation technique based on generative adversarial networks (GANs). We apply these neural networks to the modeling of electromagnetic showers in a longitudinally segmented calorimeter, and achieve speedup factors comparable to or better than existing full simulation techniques on CPU (100×-1000×) and even faster on GPU (up to $\sim 10^5\times$). There are still challenges for achieving precision across the entire phase space, but our solution can reproduce a variety of geometric shower shape properties of photons, positrons and charged pions. This represents a significant stepping stone toward a full neural network-based detector simulation that could save significant computing time and enable many analyses now and in the future.

The situation today

- **Deep Learning-based fast simulation is a reality**
 - Large number of prototypes for different experiments
- **Need to bring it to production level**
 - Establish **validation process** and evaluate systematics
 - Metrics, benchmarks, ..
 - Design **integration** in (fast) simulation frameworks
 - Work already ongoing in Geant4 (D. Salamani, A. Zaborowska)
 - Evaluate **computing resources**
 - Fair comparison to state-of-the-art, resource budget
 - **Generalisation**
 - How to move beyond the "one use case - one prototype" approach?

Validation metrics

- Measure difference between **model and real PDF**
 - Kullback-Leibler Divergence
 - Inception score, Fréchet Inception Distance
 - Maximum Mean Discrepancy
 - Structural Similarity Index
 - ...
- Compare **physics distributions to MC**
- Investigate **different aspects**
 - Mixing and coverage (sample diversity)
 - Saliency
 - Mode collapse or mode dropping
 - Overfitting (has the network memorized samples?)

Self-Attention GANs for LHCb calorimeter

The Laboratory of Methods for Big Data Analysis

PRD-AUC

- P, Q – real and generated distributions
- ν_Q, ν_P – loss in precision and loss in recall
- $\alpha, \beta \in (0,1)$ – precision and recall
- $P = \beta\mu + (1 - \beta)\nu_P \quad Q = \alpha\mu + (1 - \alpha)\nu_Q$
- Precision Recall Distribution [5] – all attainable pairs (α, β)
- PRD Area Under Curve (Q, P) characterizes trade-off between precision and recall

Sajjadi, Mehdi SM, et al. "Assessing generative models via precision and recall." *arXiv preprint arXiv:1806.00035* (2018).

- Different approaches and techniques
- Research not restricted to generative models

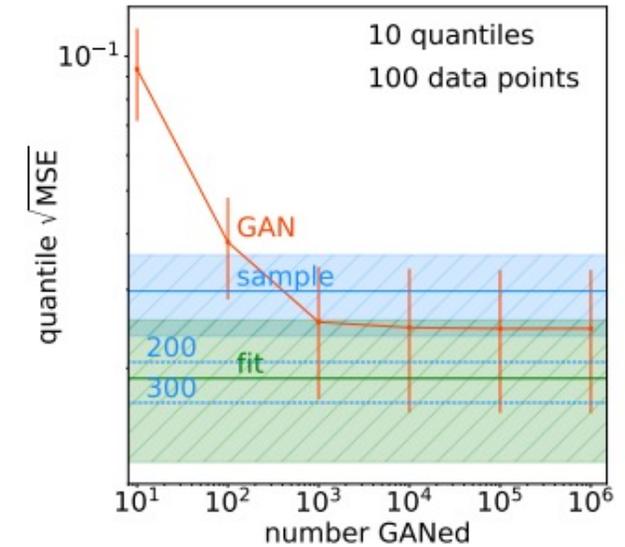

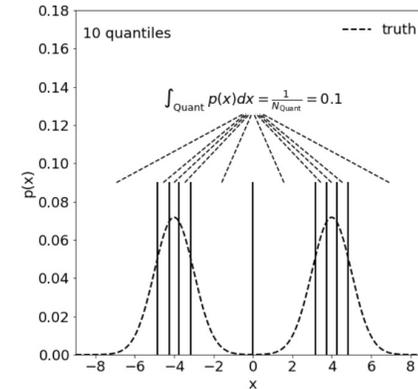

Kendal, Gal, NIPS 2017,
<https://papers.nips.cc/paper/2017/file/2650d6089a6d640c5e85b2b88265dc2b-Paper.pdf>

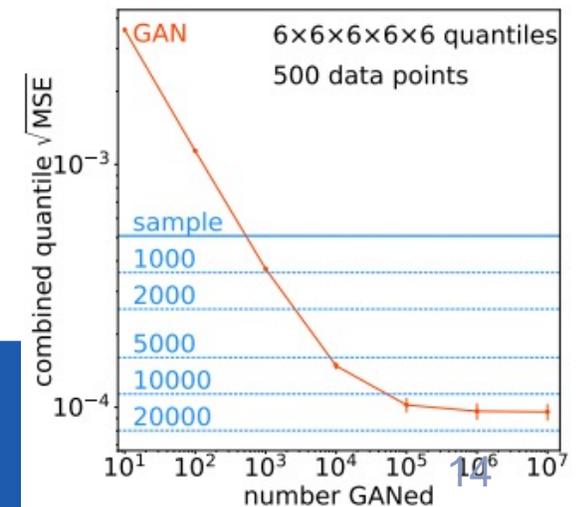

Systematics: training dataset size

- If a GAN is trained on **N** data points, how many **new** points can be drawn?
- GAN can describe distribution better than training data
- Needs 10,000 GAN points to match 150 true points
- In terms of **information**:
 - **sample**: only data points
 - **fit**: data + true function
 - **GAN**: data + smooth, continuous function

Most physics data sets described by continuous function → GAN can interpolate

Generalisation to multi-dimensional problem

Systematics: image similarity

GAN can exhibit **mode-collapse** or **mode-drop**

How much **diversity** in the generated sample?

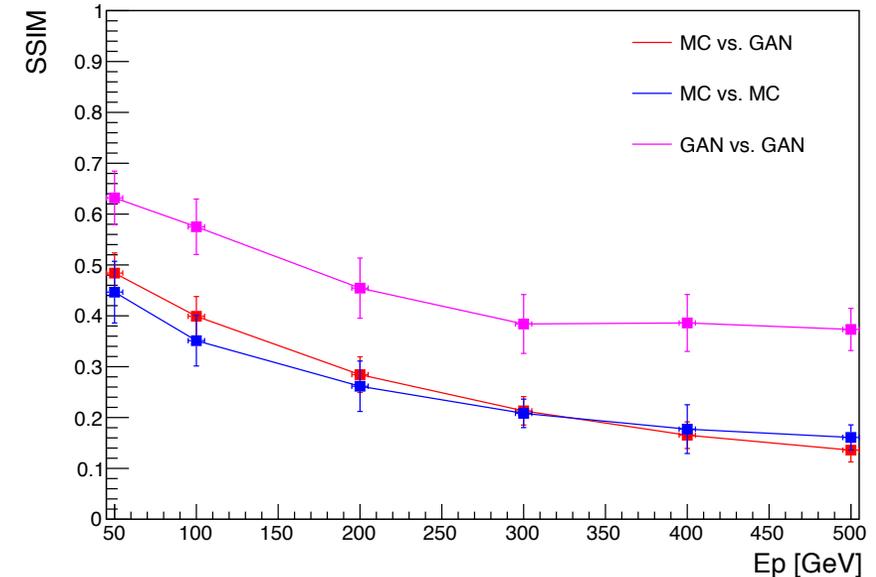

- Use the **Structural Similarity Index**

$$\text{SSIM}(x, y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)}$$

where x, y are two samples to be compared

- Calculated on sliding windows, then averaged.
- Ours is a 3D problem: SSIM computed in **xy plane**, 3rd dimension is **channel**
- Adjust C1-C2 to the pixel dynamic range

SSIM: L=0.0001 Angle=90°

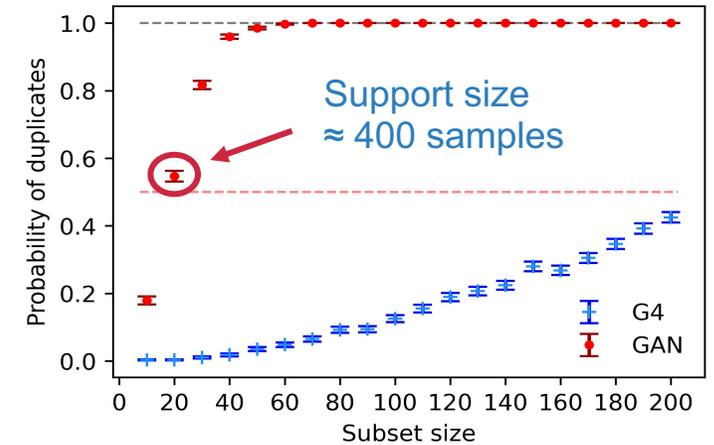

$$\text{SSIM}(x, y) = 1 \Leftrightarrow x = y$$

Systematics: Support size

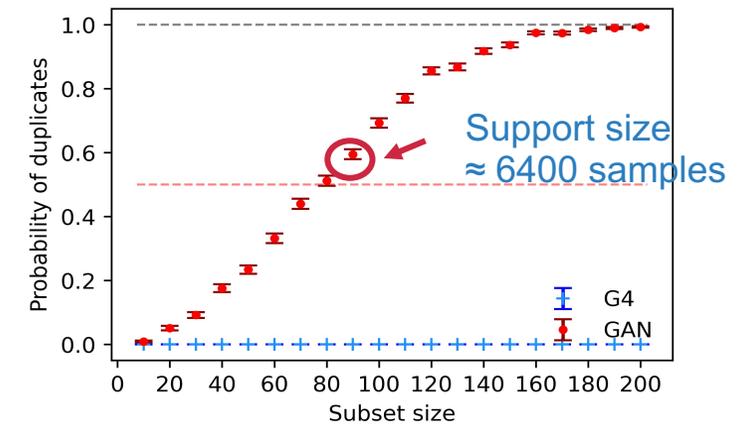

Empirical evidence of the GAN **low support size** (Arora and Sanjeev, 2017)

- Learnt distribution not representative enough
- Use Birthday paradox test to measure GAN support size
- GAN samples significantly more similar → **smaller** support size
- Test depends strongly on **duplicates definition**

Not adapted to our problem?

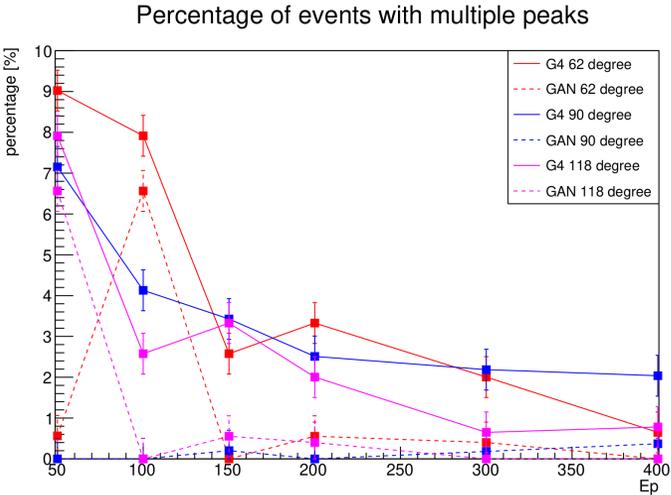

Energy-based duplicate definition

SSIM –based duplicate definition

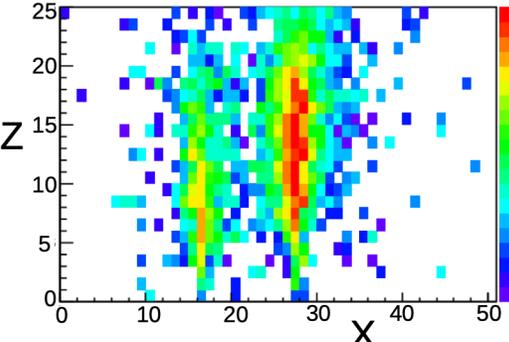

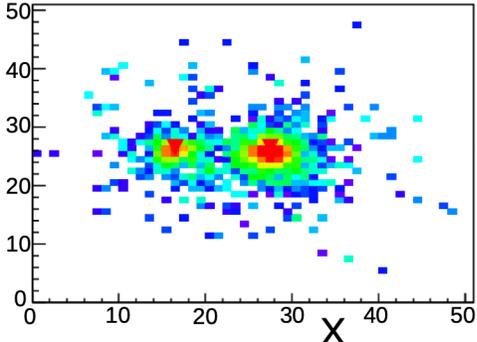

Systematics: rare events

In some cases it is important to reproduce correctly the topology and occurrence of rare events

Development directions

ML/DL have their origins in the studies on the human brain, but today
DL doesn't learn like humans do.

Current research in DL tries to improve on this aspects

G. Hinton, Y. Le Cunn, Y. Bengio , AAI 2020 keynotes, Turing Award Winners Event
<https://www.youtube.com/watch?v=UX8OubxsY8w>

- New improvements will not be achieved by simply making models **larger and larger**
- **Alternative architectures and approaches to learning :**
 - **Few-shots learning**
 - **Self-Supervised Learning**
 - **Meta-Learning**
- **Generalisation** to different data distributions (out-of-distribution generalisation)

openAI GPT-3 as a foundation model

Generative Pretrained Transformer-style autoregressive model

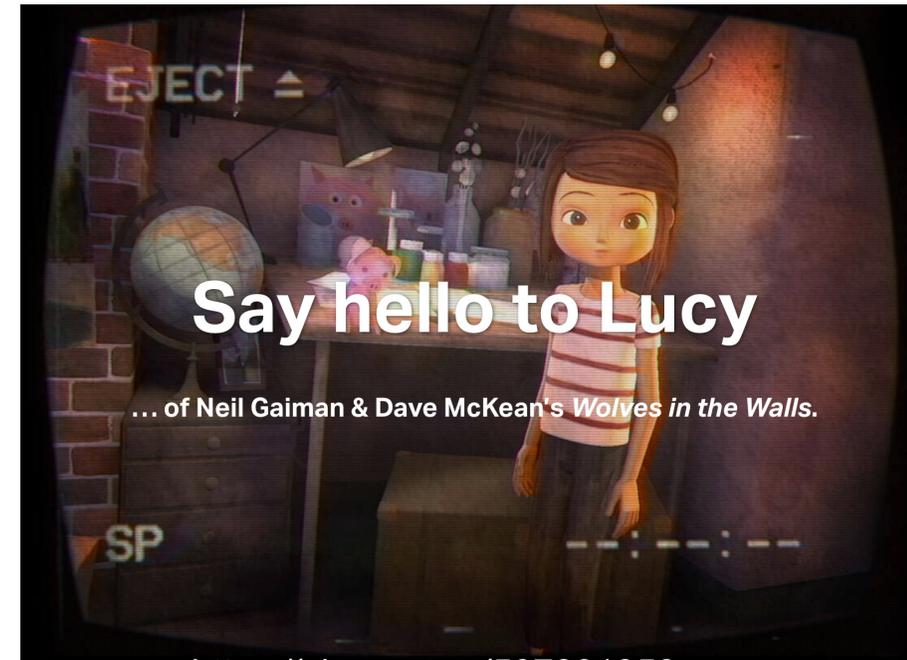

175 billion parameters

Previously largest model was **Microsoft's Turing NLG**, with 17 billion parameters (Feb. 2020)

Trained with large Internet data sets to perform multiple **downstream tasks**

A “foundation” model

Brown, Tom B., et al. "Language models are few-shot learners." *arXiv preprint arXiv:2005.14165* (2020).

Can we build **foundation models** for detector simulation?

Summary

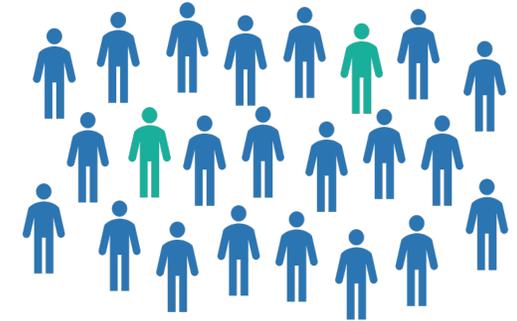

- Research in the past few years has proven **generative models can be used for (fast) simulation**
 - **Large range of applications** beyond detector simulation: direct analysis-level event generation, reconstruction-level features, optimisation,...
- Efforts needed to achieve **full integration** in simulation frameworks
 - Lots of initiative and already some results
- Those are **very exciting times** for Deep Learning
 - We should continue core research on models
 - Follow general research directions and apply them to our field.

Thanks!

Sofia.Vallecorsa@cern.ch

Systematics: Support size

Empirical evidence of the GAN **low support size** (Arora and Sanjeev, 2017)

- Learnt distribution not representative enough
 - Use Birthday paradox test to measure GAN support size
- Birthday paradox test** (Brink, 2012):

How many people need to be in one room so that $P(\text{at least two people have same birthday}) > 0.5$?

- 365 days in a year \rightarrow 23 people is enough

Generalized problem:

How many samples is it necessary to generate to have $P(\text{at least one pair of duplicates among the samples}) > 0.5$?

- **(The answer)²** = estimate of the support size

Birthday paradox for GANs

Original birthday paradox problem

- Days in a year – **finite set** of possible values with discrete uniform distribution
- **Unique duplicates definition** – people born on the same day

Exact duplicates

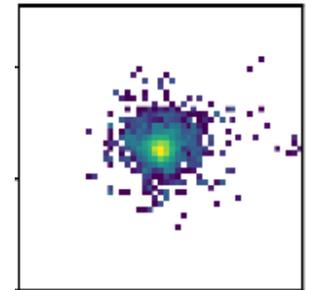

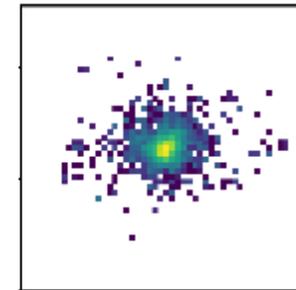

July 4

July 4

GAN distribution

- Images – pixels of **continuous values**
- **Multivariate continuous distribution** → occurrence of exact duplicates has zero probability
- Duplicates as “similar enough” images

Not exact duplicates
But similar enough?

Similarity metrics depend on the use case and data type
