## PNMR Status Update

Mingyu Chen<br>University of Virginia<br>March 25, 2021

## Outline:

1. Introduction of PNMR
2. PNMR calibration during experiment
3. PNMR online results
4. PNMR offline analysis
5. Post experiment PNMR loss study
6. Future work

## Pulse NMR Polarimetry

## Advantage:

- Took shorter time to complete measurement, less depolarization compare to AFP-NMR.
- For future metallic end cells, provide local polarimetry at transfer tube.

## Principle:

- Send a RF pulse at Larmor frequency which tips ${ }^{3} \mathrm{He}$ spin away from holding field axis: $\quad \theta_{\text {tip }}=\frac{1}{2} \gamma H_{1} t_{\text {pulse }}$
- When pulse ends, the spin precesses back to its initial state and experience free induction decay (FID).
- FID signal is picked up by the PNMR coil. Measure the transverse component of magnetic moment proportional to ${ }^{3} \mathrm{He}$

$$
S(t) \propto M_{z} \sin \left(\theta_{t i p}\right) \cos \left(\omega t+\phi_{0}\right) e^{-t / T_{2}}
$$ polarization.

## PNMR Calibration during Experiment

- With established EPR vs NMR calib, NMR gives ${ }^{3} \mathrm{He}$ polarization (\%) at measurement location.
- PNMR was performed at transfer tube which was calibrated by AFP-NMR at pumping chamber.
- PNMR calibration sequence:

1. PNMR measurement;
2. Wait 1 min ;
3. NMR measurement

- For production run, PNMR calibration was performed every 4 or 5 hours for each production run condition (cell, SHMS kinematic)

- Current fit for the signal by the FID fitting function to obtain PNMR amplitude

$$
S(t)=F I D(t)=A_{0} \cos \left(\omega t+\phi_{0}\right) e^{-t / T_{2}}+a * t+b
$$

- Obtain $\mathrm{PNMR}_{\text {amp }} /$ NMR $_{\text {amp }}$ ratio in order to calibrate PNMR with NMR.

Note:

- Have 4 or 5 sets of PNMR vs. NMR measurements in order to determine PNMR calibration constant (in $\% / \mathrm{mV}$ )
- For offline analysis will also study PNMR vs. NMR at target chamber calibration.

## Holding Field Stability

- Different SHMS HB kinematics results different Holding field gradient around the PNMR coil region, thus PNMR vs NMR calibration need to be done for each SHMS HB kinematics setting.
- For same Holding field direction and same SHMS HB kinematics, the Holding field coil current still drifts (with 0.01 A level) after wait several hours to let the coil warm up.
(this is main due to the power supplies for holding field coils are in voltage control mode)
- Holding field current can only be fine tune at $\pm 0.02$ A level due to limitation of voltage control mode of the power supplies.

- 180 deg with HB at 14.5 deg, -6.4 GeV . HS current varies from -7.288 A to 7.280 A.
- pNMR_He_20200831_004832: HS=$7.284 \overline{\mathrm{~A}}$; Pulse freq $=82 \overline{2} .265 \mathrm{kHz}$, Reference freq=81.98 kHz; FID freq=101.199 Hz (Larmor freq ~82.081 kHz )
- pNMR_He_20200831_053435: HS=7.280A; Pulse freq=82.045 kHz, Reference freq=81.76 kHz; FID freq=163.842 Hz (Larmor freq ~81.923 kHz)
- Will have about 316 Hz FID freq shift due to holding field coil current drift over time.
Pol ${ }^{3} \mathrm{He} \mathrm{A}_{1}{ }^{\mathrm{n}} / \mathrm{d}_{2}{ }^{\mathrm{n}}$ Collaboration Meeting
Page:4

## FID Freq Correction On Signal Amp <br> (with respect to PNMR Pulse freq)

- For ${ }^{3} \mathrm{He}$ Larmor freq in Holding field H :

$$
\omega=-\gamma H
$$

where $\mathrm{y}=-3.2434 \mathrm{kHz} / \mathrm{G}$ is 3 He gyro-magnetic ratio.

- This means for holding field drift be about 30 mG around PNMR coil region, we will have about 100 Hz freq shift for ${ }^{3} \mathrm{He}$ Larmor freq.
- The usage of a Lock-in amplifier makes the frequency for obtained FID signal becomes difference between Larmor freq and Lock-in amplifier reference freq.
- From initial PNMR vs NMR calibration, noticed PNMR FID signal amp become higher when FID signal frequency become lower due to ${ }^{3} \mathrm{He}$ tipping angle change.
- Tried to use a linear model to correct amplitude for different FID signal frequency.

$$
A_{\text {corr }}=A_{0} *\left(1+c \frac{f_{F I D}-\Delta f}{\Delta f}\right)
$$

Where $A_{0}$ is the fitted FID amp, $f_{\text {FID }}$ is FID signal freq, $\Delta f$ is the difference between pulse freq and reference freq. Constant c is the factor for signal amp change.

Note: for PNMR system set up, set the reference freq $\sim 335 \mathrm{~Hz}$ below the pulse freq.

## PNMR vs NMR Calibration Results

Note: "*" means only have one or two sets of PNMR vs. NMR measurement, maybe not enough to determine calibration constant.

## PNMR Online Analysis

(for $\mathrm{d}_{2}{ }^{\mathrm{n}}$ experiment E12-06-121)
 Time

- PNMR was performed at transfer tube which was calibrated by AFP-NMR at pumping chamber. For most of the measurements, polarization from PNMR agrees with NMR within $\pm 2 \%$.
- However, due to the limitation of holding field power supply, the drift of holding field magnitude over time changed PNMR signal amplitude and introduce additional uncertainty.
- Still need to do detailed analysis to characterize this effect on PNMR signal and determine the systemic uncertainty for PNMR.

## Zero-Crossing Algorithm <br> (with "Umass-ZC" program)

- Midpoint: Take the average time of samples before and after the zero crossing
- Linear interpolation: Compute the zero crossing time based on linearly-interpolating across the zero crossing region
- Least squares: Perform a least-squares fit to the samples in the immediate vicinity ( $\sim 1 / 8$ of a period) of a given zero crossing. This tends to be the best result (that is, more accurate).

Count number of zero crossings of the PNMR signal between given start and stop times to determine FID freq:

$$
f=\frac{N_{z c}-1}{2 \Delta t}
$$

Where $N_{z c}$ is number of zero crossings
and $\Delta t=t_{\text {end }}-\mathrm{t}_{\text {start }}$
phase fit:

- plot determined zero crossings against time of crossing. Then the slope of line gives frequency at $\mathrm{t}=0$ msec.

## Determine PNMR freq:

- Using Least-squares (with phase fit) to determine the PNMR freq

## PNMR FID Signal Freq

## (on Cell Briana 09/20)

- File_name:pNMR_He_20200920_101857
- Holding field at 0 deg with SHMS HB at 13 deg, -2.1286 GeV
- Correction coils: VL=0.0A, VS=0.0A; Pulse freq=81.465 kHz, Ref freq=81.13 kHz
- FID Freq=558.228 Hz (from UMass-ZC)

Goal: Help characterize drift of holding field magnitude. Since PNMR FID signal freq is Larmor freq of ${ }^{3} \mathrm{He}$ at time of measurement.

## PNMR FID Amplitude Analysis <br> (Signal Deconvolution by Probabilistic Sparse Matrix Factorization)

- For PNMR FID raw signal, it contains a signal component which decays exponentially with time, while the noise component is a random or flat value.
- Then after applying short time Fourier transform (STFT) to the raw signal, we could perform probabilistic sparse matrix factorization (PSMF) to separate the noise from signal.
- Finally, do inverse Fourier transform (inverse STFT) of the signal component to obtain the deconvoluted signal.

Goal: separate noise component from signal component; determine FID amp for signal component only to reduce uncertainty.

- Signal Deconvolution and Noise Factor Analysis Based on a Combination of Time-Frequency Analysis and Probabilistic Sparse Matrix Factorization (by Shunji Yamada etal)

## Flow Chart of Signal Deconvolution Method

- Signal Deconvolution and Noise Factor Analysis Based on a Combination of Time-Frequency Analysis and Probabilistic Sparse Matrix Factorization (by Shunji Yamada etal)

## PNMR FID Amplitude Analysis <br> (Signal Deconvolution by Probabilistic Sparse Matrix Factorization)

- Fitted FID amp: $\mathrm{A}_{0}=1.033 \mathrm{~V}$ (PNMR signal component; t=5 ms to 20 ms )

Note:

- Take raw PNMR signal up to 1.0 sec ; Should extract noise after signal decays away.
- Could apply a FFT cut on low freq to improve the PNMR signal.

## PNMR Loss Study During the Experiment

 (on Cell Austin and Cell Tommy)
## PNMR Loss study:

Note: "*" means that PNMR loss is not finalized yet.
Goal: Help determine the in beam 3He polarization after PNMR and NMR measurements.

1) Since PNMR loss per measurement depends on the PNMR ${ }^{3} \mathrm{He}$ spin tip angle, the holding field magnitude drift will affect the PNMR loss.
2) PNMR loss study during the experiment is not ideal for determine PNMR loss.
3) Need to do additional post experiment PNMR loss study at EEL target lab to finalize the PNMR loss per measurement during the experiment.

## Post Experiment PNMR Loss Study <br> (plan at EEL Target Lab)

PNMR Loss Measurement: during Hot spin down with convection
a) NMR measurement at $0 \mathrm{~min}: \mathrm{P}_{0}=\beta_{2} \mathrm{P}_{\mathrm{a}}$
b) 10 PNMR measurements take within 1 sec at 1 min : (for $\mathrm{T} 2 \sim 7 \mathrm{msec}$ )
c) NMR measurement at $30 \mathrm{~min}: P(t)=\mathrm{P}_{\mathrm{c}}$
d) NMR measurement at $60 \mathrm{~min}: \mathrm{P}_{\mathrm{d}}$

For $\tau$ be Hot spin down time constant and known $\beta=1-$ AFP $_{\text {Loss }}$ (NMR AFP loss per sweep)

Then from c ), d) get $\mathrm{P}_{0}$ ' after all PNMR measurement: ( $\Delta \mathrm{t}=0.5 \mathrm{hr}$ )

$$
\begin{aligned}
& P_{0}{ }^{\prime}=P_{c} e^{-\Delta t / \tau} \\
& P_{d}=P_{c} \beta^{2} e^{-\Delta t / \tau}
\end{aligned} \longrightarrow P_{0}{ }^{\prime}=\frac{P_{c}^{2} \beta^{2}}{P_{d}}
$$

Polarization time evolution:
Using a), c) to found out PNMR ${ }^{3} \mathrm{He}$ spin tip angle: $(\mathrm{n}=10)$

$$
P(t)=P_{0} e^{-t / \tau}
$$

$$
P_{0}^{\prime}=\left(1-\cos \left(\theta_{\text {tip }}\right)\right)^{n} * P_{0}
$$

Thus PNMR loss per measurement is:

$$
\alpha_{\text {loss }}=1-\cos \left(\theta_{\text {tip }}\right)=\left(\frac{P_{0}{ }^{\prime}}{P_{0}}\right)^{1 / n}
$$

## Future Work

- For PNMR analysis, still in the process of offline detailed analysis with main effort focused on obtain PNMR FID amplitude and determine PNMR systemic uncertainty.
- In addition, post experiment PNMR loss tests are planned to perform in EEL target lab to help determine the PNMR loss per measurement during the experiment.

## PNMR Loss Study During the Experiment (On Cell Austin and Cell Tommy)

PNMR Loss Measurement:
a) NMR measurement at $0 \mathrm{~min}: \mathrm{P}_{0}=\beta_{2} \mathrm{P}_{\mathrm{a}}$
b) 5 PNMR measurements take every min: (from 1 min till 5 min )
c) NMR measurement at $15 \mathrm{~min}: \mathrm{P}(\mathrm{t})=\mathrm{P}_{\mathrm{c}}$
d) NMR measurement at $30 \mathrm{~min}: P_{d}$

For $\tau$ be Hot spin up time constant and $\beta=1-A F P_{\text {Loss }}$ (NMR AFP loss per sweep)
Then from c$)$, d) get $\mathrm{P}_{\text {max }}$ : $(\mathrm{t}=0.25 \mathrm{hr})$

$$
P_{\max }=\frac{P_{d}-\beta^{2} P_{c} e^{-t / \tau}}{1-e^{-t / \tau}}
$$

Polarization time evolution:

$$
P(t)=P_{0}+\left(P_{\max }-P_{0}\right)\left(1-e^{-t / \tau}\right)
$$

Using a), c) to found out PNMR loss. ( $\mathrm{n}=5$ )

$$
P_{0}^{\prime}=\frac{P(t)-P_{\max }\left(1-e^{-t / \tau}\right)}{e^{-t / \tau}} \quad P_{0}^{\prime}=\left(1-\alpha_{\text {loss }}\right)^{n} * P_{0}
$$

Thus PNMR loss is: $\alpha_{\text {loss }}=1-\left(P_{0}{ }^{\prime} / P_{0}\right)^{1 / n}$

## PNMR System Setup <br> (for PNMR Loss Study at EEL target Lab)

1) Modify the current Labview program for PNMR measurement to be able to perform 10 PNMR measurements within 1 sec . (send 10 PNMR RF pulses with $\mathrm{t}_{\text {pulse }}=1 \mathrm{msec}$ with $\mathrm{dt}=100 \mathrm{msec}$ )
2) Use Agilent power supply with current control mode to provide similar holding field coil current level during $\mathrm{d}_{2}{ }^{\mathrm{n}}$ experiment. (Holding field magnitude will not be exactly at 25.0 G )
3) Use horizontal correction coils to add holding field gradient up to $\sim 30 \mathrm{mG} / \mathrm{cm}$ at PNMR coil region.
4) Establish similar convection condition (for cell Austin convection heater at 9 V ; for cell Tommy convection heater at 7 V )
5) Test with different PNMR RF pulse freq (different df away from 3 He Larmor freq) to determine the effect of df on ${ }^{3} \mathrm{He}$ spin tipping angle $\theta_{\text {tip }}$.

## Note:

With established relation between df and $\theta_{\text {tip }}$, we could determine PNMR loss for all the PNMR measurements during $\mathrm{d}_{2}{ }^{\mathrm{n}}$ experiment. (with known Fitted PNMR FID freq)

## Typical PNMR FID Signal

 (with PNMR coil on Cell Tommy)

- Typical PNMR signal and signal fit
- Condition: pulse freq= 82.385 kHz , RF freq=81.98 kHz, t_pulse=1 ms, df=405 Hz
- Target spin 90deg with HB on for 18 deg, 5.6 GeV
- $\mathrm{VL}=4.4 \mathrm{~A}, \mathrm{VS}=6.0 \mathrm{~A}$ with convection at 7 V
- Current fit for the signal by the FID fitting function to obtain PNMR amplitude $A_{0}$.

$$
S(t)=F I D(t)=A_{0} \cos \left(\omega t+\phi_{0}\right) e^{-t / T_{2}}+a * t+b
$$

- Obtain PNMR_amp/NMR_amp ratio in order to calibrate PNMR with NMR.

## PNMR with Lockin SR844 and DAQ Setup

Counting Rouse

- Keep Holding filed at 25G along z-direction (along beam direction) by Helmholtz coil.
- For Preamplifier the bandpass is 10 kHz to 100 kHz ; the preamplifier has gain of 20 times.
- The input pulse sine wave signal from DS 345 has $\mathrm{f}_{\mathrm{in}}=81.085 \mathrm{kHz}, \mathrm{V}_{\mathrm{rms}}=0.3 \mathrm{~V}$ with $t_{\text {pulse }}=1.0 \mathrm{~ms}$; while the reference signal for Lockin is from the sync of HP3324A with $f_{R}=80.8 \mathrm{kHz}$.
- RF switches: ZYSWA-2050DR controlled by TTL low/ high signal. If TTL signal is high, function generator will send the input pulse to the PNMR coil. When the TTL is low, FID signal from the PNMR coil will pass the second RF switch, then go through the rest setup.

## ${ }^{3} \mathrm{He} \mathrm{Tipping} \mathrm{Angle}$

(From Nguyen Ton's presentation 05/23/2016)

## Red: experiment, Blue: theory

Conclusion: for this coil, $90^{\circ}$ pulse is at $t_{\text {pulse }} \sim 0.7 \mathrm{~ms} .360^{\circ}$ pulse at $\mathrm{t}_{\text {pulse }}=2.8 \mathrm{~ms}$.
Note: Map of $\mathrm{t}_{\text {pulse }}$ from 0.4 msec to 3.0 msec with step $0.1 \mathrm{msec} . \quad \theta_{\text {tip }}=\frac{1}{2} \gamma H_{1} t_{\text {pulse }}$
