# **HUGS2021: Grid Computing**

Malachi Schram, Ph.D. Department of Data Science Thomas Jefferson National Accelerator Facility

June 2, 2021

Distributed Computing:

- -Belle II US computing
- Project 8 computing

**Design and Control:** 

- -Accelerator control using reinforcement learning
- Exascale reinforcement learning
- -Water cluster and material property optimization

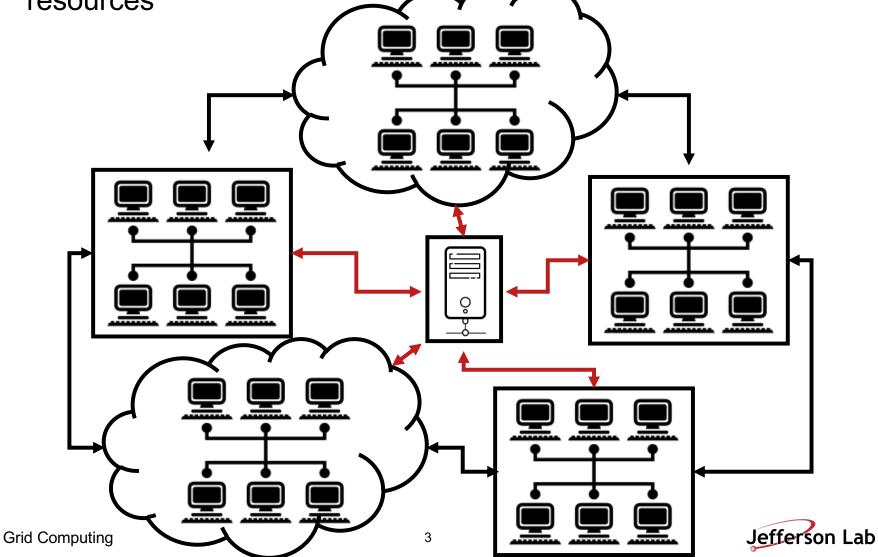

Machine Learning:

- -Anomaly detection and prognostication
- Segmentation, object identification, classification
- Domain aware ML

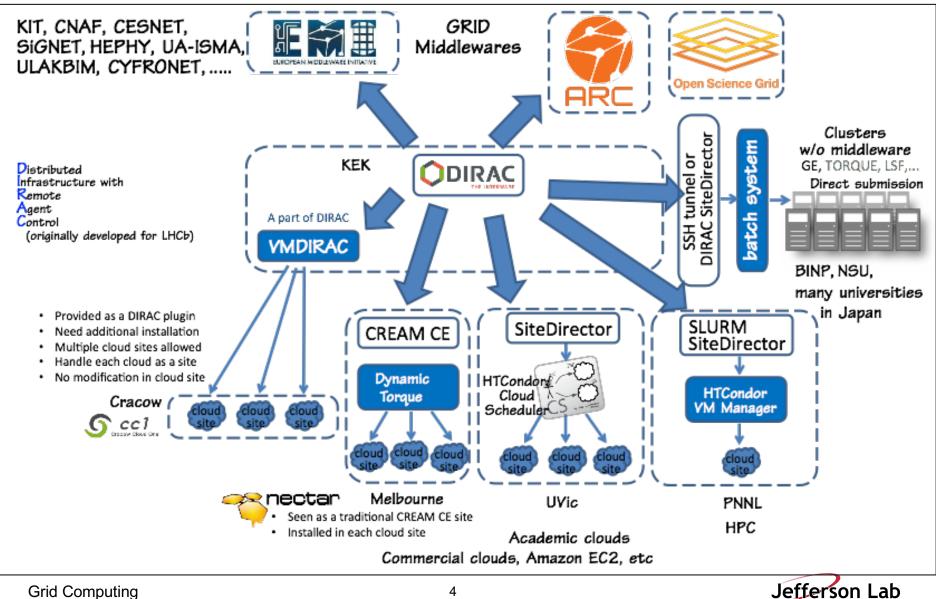

### What is Distributed Computing?

Coordinated collections of geographically distributed computing resources

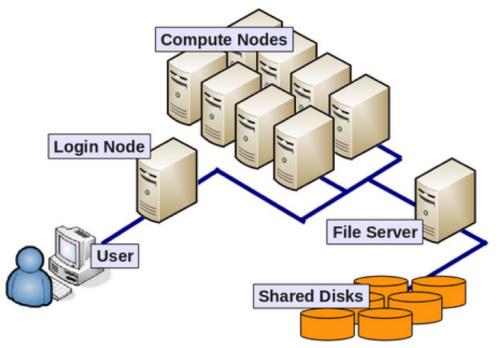

### **Real world example**

Grid Computing

# Starting with conventional scientific computing

- User node:
  - Terminal to access the local cluster using site defined authentication
- Login node and job scheduler (SLURM, HTCondor, Torque, etc.)
  - Requires permission to access
  - Head node(s) are used to submit jobs
    and run very limited test jobs
- Compute nodes:
  - Executes the computational work
  - OS, libraries, etc.
  - Software access (either on shared storage or on each individual node)
- Shared storage (Lustre, NFS, Ceph, etc.)
  - Typically visible throughout the cluster Grid Computing

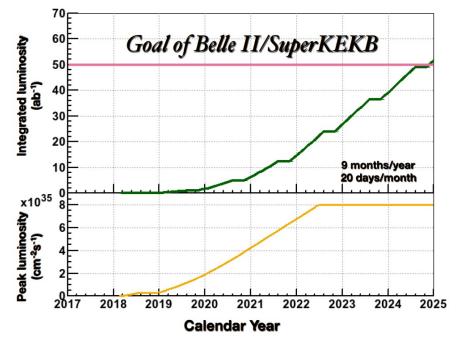

We need to coordinate computing resources across various sites. Here are a few things to consider:

- -Resource requirements and allocation
- -Authentication services
- Computing resources and software distribution
- -Data storage, transfers, and bookkeeping
- -Grid Orchestration
- Workflow automation

# **Resource Estimations**

- Large scientific projects such as the LHC experiments, Belle II, and soon EIC have incredible computing requirements.
- Example from Belle II:

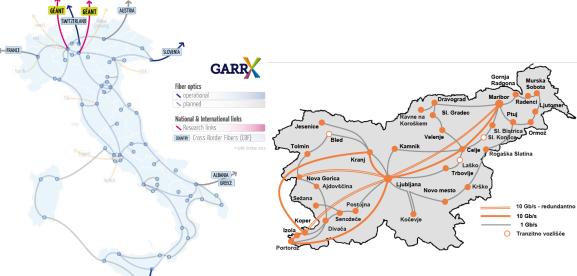

- Resource requirements depend upon luminosity profile & event size (data volume), (re)processing, MC generation, and user analysis
- MC production accounts for nearly 50% of US Belle II CPU
- Potentially use Leadership Class Facilities (LCFs) for MC production

	CY17	CY18	CY19	CY20	CY21
CPU [kHEPSpecs]	20.11	27.56	58.90	69.71	82.97
Storage [PB]	0.31	0.81	5.04	6.50	9.28
Networking In/Out [Gbps]	0.30/0.30	0.49/0.36	1.06/0.26	1.56/0.31	1.89/0.83

Grid Computing

### **Coordinating network resources providers**

- Workshops are organized between compute sites and networking providers
- The purpose of these workshops are preparation for addressing the wide-area networking requirements
- Example report can be found at:
  - <u>http://www.es.net/assets/pubs\_presos/Belle-II-Experiment-Network-Requirements-Workshop-v18-final.pdf</u>

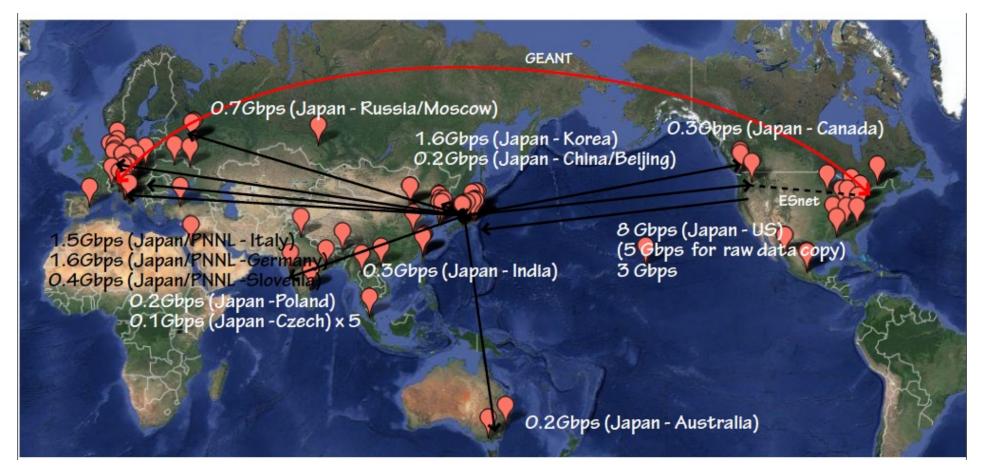

# Initial network traffic estimations

- Based on the capability at each site and local network provider
- The contributions are based on available resources and politics

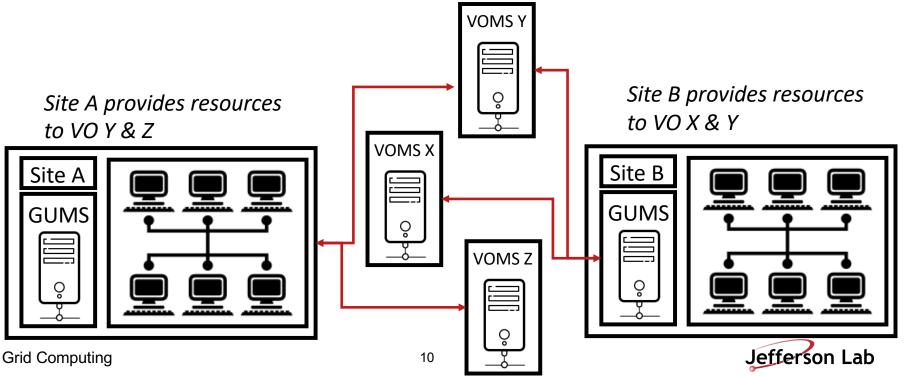

Grid Computing

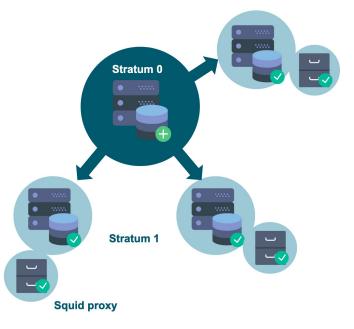

### **Virtual Organization & Authorization Services**

- Virtual Organization (VO) is a dynamic set of individuals or institutions defined around a set of resource-sharing rules and conditions.
- Virtual Organization Management System (VOMS) provide a structured account database for users, group, and Vos.
- Grid User Management System (GUMS) is a site tool that captures the VOs and associated users and policies that will be allowed access to the site.

# Computing resources and software distribution

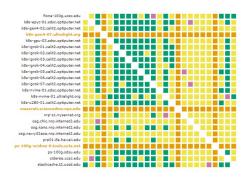

- Computing Element (gateway node):
  - Access point for information to be exchanged between the central system and the local cluster
  - Can be used as a proxy for the worker nodes to access the outside world.
  - Push and pull techniques are available depending on the grid orchestration
- Worker nodes
  - Executes the job similar to traditional cluster with some network and software requirements
- Software coordination:
  - Define OS and required libraries
    - Compilers, domain software, etc.
    - This can cause a lot of headaches if you are supporting multiple VOs
  - CernVM File System (CVMFS): (<u>https://cernvm.cern.ch/fs</u>)
    - Provides a scalable software distribution platform
    - Multi-tiered caching system for scaling
    - Stratum 0, Stratum 1, Squid servers, and clients
  - Containers (ex: https://www.docker.com/):
    - Used to decouple the hardware level OS from the project requirements
  - Hybrid approach: containers in CVMFS

### Data storage, transfers, and bookkeeping

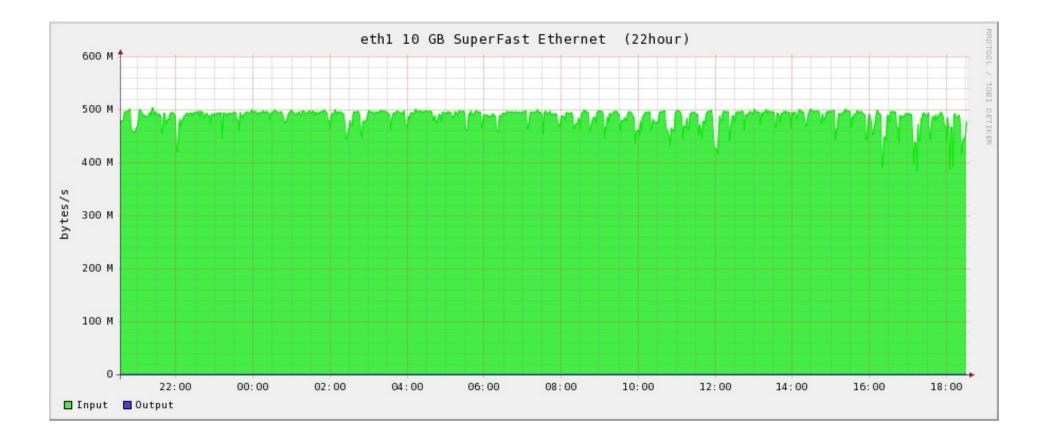

- Storage Element (SE) is used to communicate with the local storage system and coordinate data transfers
- Data transfer nodes (DTN) leverage GridFTP for data transfers
- The data location is captured using a logical file name and associated information on physical location (site, path, etc.)
- Mass data transfer is done using tools like:
  - Globus online (<u>https://www.globus.org/</u>)
  - -File Transfer Service 3 (<u>https://fts.web.cern.ch/fts/</u>) 💿 FTS
- Network monitoring:
  - -perfSONAR (https://www.perfsonar.net/)
  - -Monitoring and Debugging Dashboard (MaDDash)

### **Network Data Challenges**

• Run network stability tests to ensure there are no problems with the network and the DTN configurations and FTS setup.

# **Grid Orchestrations**

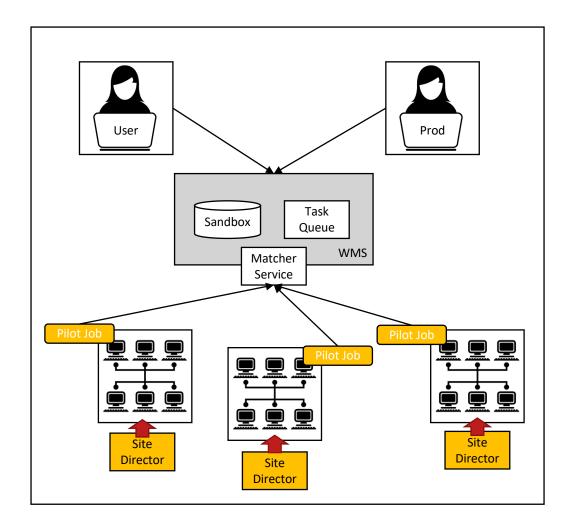

- Once you have defined the computing requirements, established an authentication protocol, and setup the relevant computing hardware. You will need to identify a mechanism to orchestrate the workflows.
- There are a lot of elements required to provide a production ready grid system.
- There are several established LHC solutions, such as DIRAC (<u>https://dirac.readthedocs.io</u>), that provide great tools to orchestrate scientific workflows:

- 1. Workload Management System (WMS)
  - Provides users job submission functionality while hiding the heterogeneity of the computing resources. Compute jobs use Pilot Jobs model
- 2. Data Management System (DMS):
  - Provides basic functionality to upload and register a local file in a StorageElement (SE) and FileCatalog (FC). Additionally, it also provides bulk data replications using FTS and retrieves achieved data on Tape for later processing.
- 3. Transformation System (TS):
  - Provides automation functionality for redundant tasks commonly related to production activities

### **Grid Orchestration Example**

•User or Prod submits jobs to DIRAC WMS.

•Sandbox stores input file(s) required to run job. This is NOT the same as input files that are available on the SEs.

•Task Queues records the job requests and associated requirements.

•Matcher Service is used to find an appropriate job based on requirements.

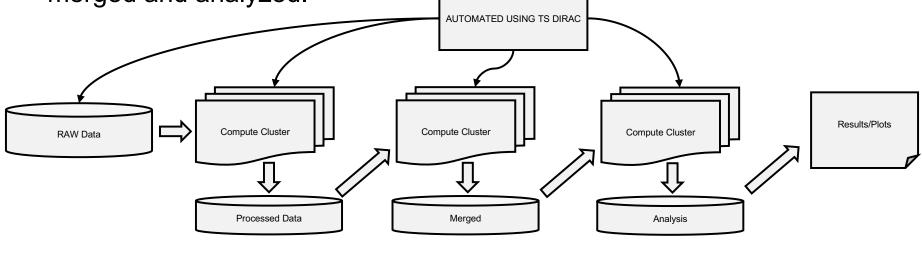

•**Pilot job** is an "empty" job used for resource reservation. Performs sanity check and enables job matching.

•Site Director submits pilot jobs to the local queue based on configuration parameters.

### **Example of Automation Workflows**

- For previous efforts, I adopted DIRAC (Distributed Infrastructure with Remote Agent Control) INTERWARE as the distributed computing workflow because it provides a complete solution and includes automation features.
- These automated features are <u>critical</u> for smaller scale experiments
- The files are registered to the DIRAC File Catalog with well defined metadata in order to trigger the raw data processing workflow. Once a data production run is finished, all raw processed files are automatically merged and analyzed.

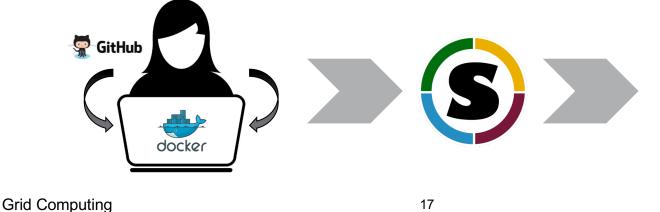

Grid Computing

Jefferson Lab

# Side note: Designing a flexible infrastructure

- The core computing services are hosted and managed using Kubernetes ٠ (https://kubernetes.io/).
- Individual containers are used to instantiate services, agent, and • databases and other core grid services.
- · Docker containers are also used to build new instances of the development and production environment.
- This provides maximal flexibility and satisfies the collaborations specific OS and libraries requirements.
- Production containers are then converted to a Singularity (https://singularity.hpcng.org/) image.
- Computation jobs are performed on the HPC clusters using a dedicated DIRAC agent mapped to the desired singularity image.
