# In my talk today:

- 1 Current state of two-photon exchange
- 2 How a positron beam at JLab can move us beyond this state

Proton form factors measurements  
show a striking discrepancy.

Proton form factors measurements  
show a striking discrepancy.

Proton form factors measurements show a striking discrepancy.

Hard two-photon exchange is  
the missing radiative correction.

Soft TPE

$e$ -vertex  
correction

$p$ -vertex  
correction

Vacuum  
polarization

Soft Bremsstrahlung

Calculations of two-photon exchange come with model dependency.

### Hadronic Approaches

- Treat off-shell propagator as collection of hadronic states.
- e.g. Ahmed, Blunden, Melnitchouk, PRC 102, 045205 (2020)

Calculations of two-photon exchange come with model dependency.

### Hadronic Approaches

- Treat off-shell propagator as collection of hadronic states.
- e.g. Ahmed, Blunden, Melnitchouk, PRC 102, 045205 (2020)

### Partonic Approaches

- Treat interaction of  $\gamma\gamma$  with quarks, distributed by GPDs.
- e.g. A. Afanasev et al., PRD 72, 013008 (2005)

Calculations of two-photon exchange come with model dependency.

### **Hadronic Approaches**

- Treat off-shell propagator as collection of hadronic states.
- e.g. Ahmed, Blunden, Melnitchouk, PRC 102, 045205 (2020)

### **Partonic Approaches**

- Treat interaction of  $\gamma\gamma$  with quarks, distributed by GPDs.
- e.g. A. Afanasev et al., PRD 72, 013008 (2005)

### **Phenomenology**

- Assume the discrepancy is caused by TPE, estimate the effect.
- e.g. A. Schmidt, JPG 47, 055109 (2020)

- e.g., E. A. Kuraev et al., Phys. Rev. C 78, 015205 (2008)

TPE can be measured through an asymmetry between  $e^+p$  and  $e^-p$  scattering.

$$\mathcal{M} = \text{[Diagram 1]} + \text{[Diagram 2]} + \mathcal{O}(\alpha^3)$$

The equation shows the scattering amplitude  $\mathcal{M}$  as a sum of two Feynman diagrams at order  $\alpha^2$ , followed by higher-order terms  $\mathcal{O}(\alpha^3)$ .  
Diagram 1 (left): A t-channel exchange of a photon (wavy line) between an incoming electron (solid line) and an incoming positron (solid line). The outgoing particles are a proton (double line) and an antiproton (double line). A grey circle marks the vertex where the photon meets the proton/antiproton lines.  
Diagram 2 (right): A box diagram representing a two-photon exchange. Two wavy lines (photons) are exchanged between the electron and positron lines and the proton and antiproton lines. Each vertex where a photon meets a fermion line is marked with a black dot. Grey circles mark the vertices where the photons meet the proton and antiproton lines.

TPE can be measured through an asymmetry between  $e^+p$  and  $e^-p$  scattering.

$$\mathcal{M} = \text{[Diagram 1]} + \text{[Diagram 2]} + \mathcal{O}(\alpha^3)$$

$$\sigma \approx |\mathcal{M}|^2 = \text{[Diagram 1]}^2 \pm 2\text{Re} \left[ \text{[Diagram 1]} \text{[Diagram 2]} \right] + \mathcal{O}(\alpha^4)$$

TPE can be measured through an asymmetry between  $e^+p$  and  $e^-p$  scattering.

$$\mathcal{M} = \text{[Diagram 1]} + \text{[Diagram 2]} + \mathcal{O}(\alpha^3)$$

$$\sigma \approx |\mathcal{M}|^2 = \left| \text{[Diagram 1]} \right|^2 \pm 2\text{Re} \left[ \text{[Diagram 1]} \text{[Diagram 2]} \right] + \mathcal{O}(\alpha^4)$$

$$\frac{\sigma_{e^+p}}{\sigma_{e^-p}} \approx 1 + \frac{4\text{Re}\{\mathcal{M}_{2\gamma}\mathcal{M}_{1\gamma}\}}{|\mathcal{M}_{1\gamma}|^2}$$

# Theory predictions for $\sigma_{e^+p}/\sigma_{e^-p}$

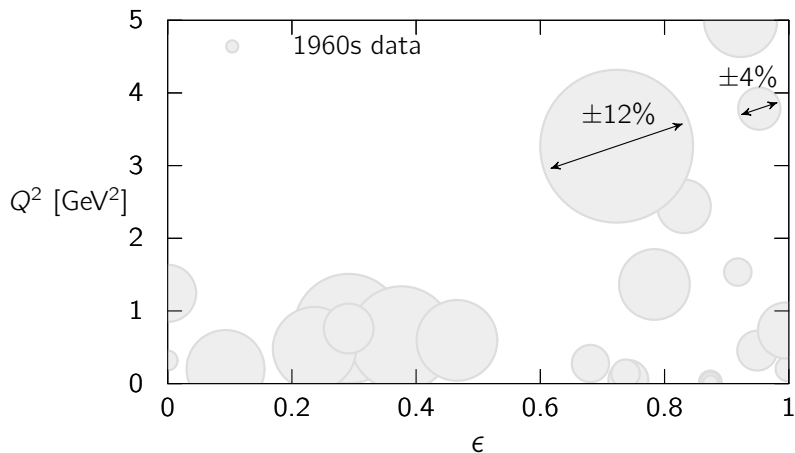

# Theory predictions for $\sigma_{e^+p}/\sigma_{e^-p}$

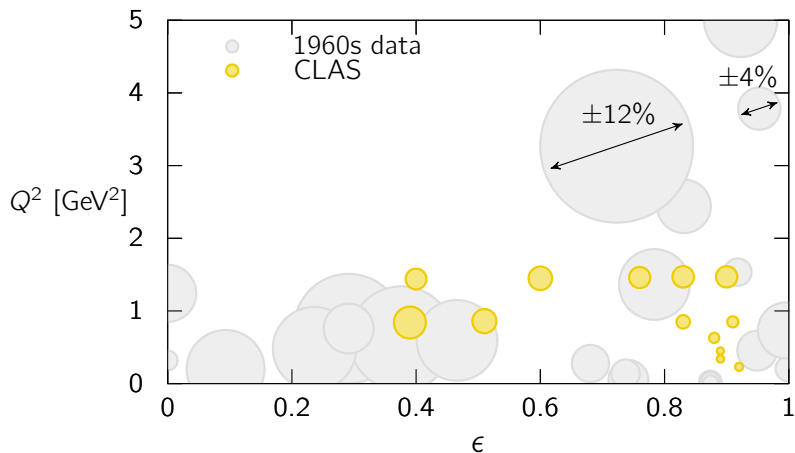

Three recent experiments measured hard TPE.

# Three recent experiments measured hard TPE.

# Three recent experiments measured hard TPE.

# Three recent experiments measured hard TPE.

# OLYMPUS observed a small TPE effect.

Henderson et al., PRL 118, 092501 (2017)

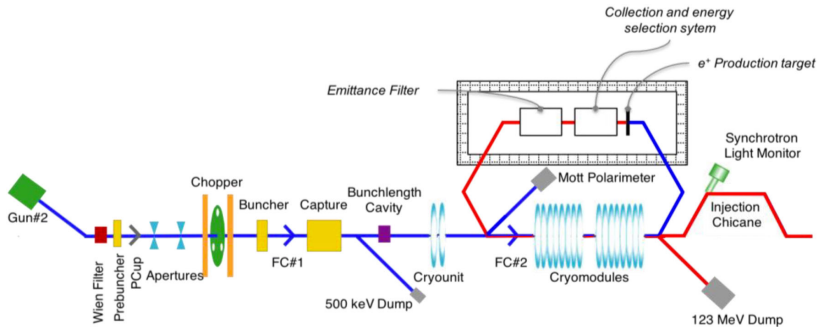

# Summary of current state

- We lack measurements where FF discrepancy is large.
- We don't have any measurements where partonic and hadronic calculations interface.
- We have no facility with a positron beam and state of the art detectors.
- We are at the cusp of a major campaign to look at 3D nucleon structure.

# In my talk today:

- 1 Current state of two-photon exchange
- 2 **How a positron beam at JLab can move us beyond this state**

# Positron beam at CEBAF with PEPPo

Design goal:

- 100 nA with  $\approx 60\%$  polarization
- Up to 1  $\mu$ A unpolarized

# Two-photon exchange concepts at Jefferson Lab

  - Imaginary part of TPE amplitude

CLAS12 is ideal for mapping TPE over a wide phase space.

CLAS12 is ideal for mapping TPE  
over a wide phase space.

Super BigBite would allow quicker measurement at the expense of coverage.

Super BigBite would allow quicker measurement at the expense of coverage.

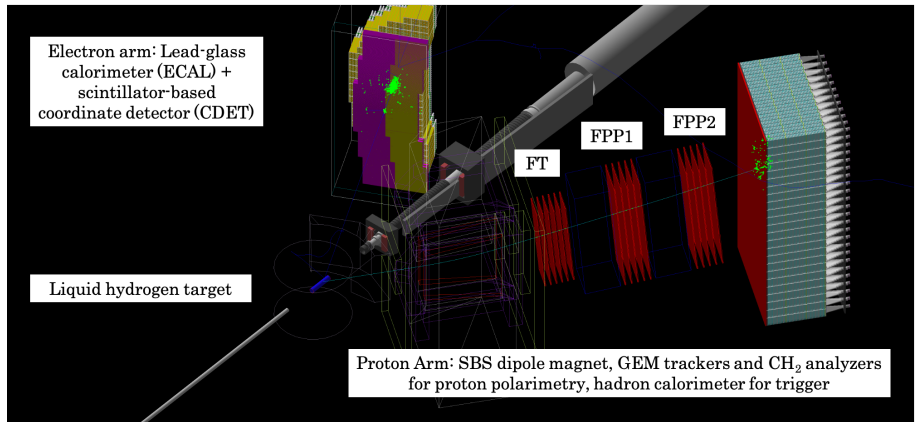

A super-Rosenbluth measurement with  $e^+$  would clearly show the bias caused by TPE.

A super-Rosenbluth measurement with  $e^+$  would clearly show the bias caused by TPE.

With Super BigBite, even  $e^+$  polarization transfer would be feasible.

$e^+$  and  $e^-$  measurements can prove if  $\epsilon$ -dependence comes from TPE.

- Sensitive to imaginary part of TPE amplitude
- Separate TPE from T-violation
- First measurement on protons at JLab

Gabe Grauvogel

Single-spin transverse asymmetries are sensitive to the imaginary part of TPE.

Target-normal:

$$A_n = \frac{\sqrt{2\epsilon(1+\epsilon)}}{\sqrt{\tau} \left( G_M^2 + \frac{\epsilon}{\tau} G_E^2 \right)} \times \left[ -G_M \text{Im} \left( \delta \tilde{G}_E + \frac{\nu}{M^2} \tilde{F}_3 \right) + G_E \text{Im} \left( \delta \tilde{G}_M + \frac{2\epsilon\nu}{M^2(1+\epsilon)} \tilde{F}_3 \right) \right] + \mathcal{O}(\alpha^4)$$

Beam Normal:

$$B_n = \frac{4mM\sqrt{2\epsilon(1-\epsilon)(1+\tau)}}{Q^2 \left( G_M^2 + \frac{\epsilon}{\tau} G_E^2 \right)} \times \left[ -\tau G_M \text{Im} \left( \tilde{F}_3 + \frac{\nu}{M^2(1+\tau)} \tilde{F}_5 \right) - G_E \text{Im} \left( \tilde{F}_4 + \frac{\nu}{M^2(1+\tau)} \tilde{F}_5 \right) \right] + \mathcal{O}(\alpha^4)$$

Transverse asymmetries do not violate parity.

Transverse asymmetries do not violate parity.

A transversely polarized proton target will require a strong holding field.

A transversely polarized proton target will require a strong holding field.

A measurement at JLab would cover new ground.

A measurement at JLab would cover new ground.

A measurement at JLab would cover new ground.

A measurement at JLab would cover new ground.

# To recap:

- Discrepancy in proton FFs may be caused by TPE.

# To recap:

- Discrepancy in proton FFs may be cause by TPE.
- Measurements up till now have been inconclusive.

# To recap:

- Discrepancy in proton FFs may be caused by TPE.
- Measurements up till now have been inconclusive.
- A positron beam at JLab would definitively map TPE, and open up new observables.

# To recap:

- Discrepancy in proton FFs may be caused by TPE.
- Measurements up till now have been inconclusive.
- A positron beam at JLab would definitively map TPE, and open up new observables.

# Conclusions:

- The proton form factor discrepancy is uncomfortable, both for high- $Q^2$  form factors and for the upcoming campaign to map 3D nucleon structure.

# Conclusions:

- The proton form factor discrepancy is uncomfortable, both for high- $Q^2$  form factors and for the upcoming campaign to map 3D nucleon structure.
- The most interesting and useful TPE measurements are  $3 \leq Q^2 \leq 5$   $\text{GeV}^2$ , to build a bridge between hadronic and partonic theory models.

# Conclusions:

- The proton form factor discrepancy is uncomfortable, both for high- $Q^2$  form factors and for the upcoming campaign to map 3D nucleon structure.
- The most interesting and useful TPE measurements are  $3 \leq Q^2 \leq 5$   $\text{GeV}^2$ , to build a bridge between hadronic and partonic theory models.
- A positron beam at Jefferson Lab would allow conclusive measurements as well as open up new observables.
