  - RCS Compton
  - Mott Polarimeters

SPIN 2023 September 24-29, 2023

# **EIC Beam Properties and Polarimetry Challenges**

EIC will provide unique challenges for electron polarimetry

- → 10 ns between electron/hadron bunches at high luminosity configuration (~40 ns at higher CM configuration)
- $\rightarrow$  Intense beams (0.26 to 2.5 A)
  - → Large synchrotron radiation for electron beams result in large effects at detectors

**Requirements:** 

- → Bunch-by-bunch measurement of polarization
- $\rightarrow$  Simultaneous measurement of both  $P_L$  and  $P_T$
- → Measurement fast enough to achieve 1% statistics for each bunch
- → Systematics *dP/P* = 1% or better

### Electron energies = 5, 10, 18 GeV

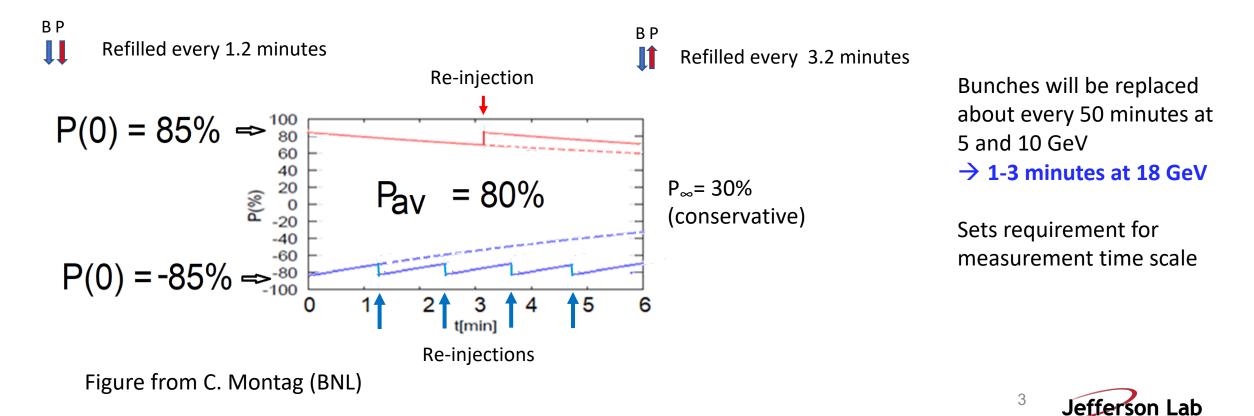

Table 1.1: Maximum luminosity parameters.

Parameter	hadron	electron	
Center-of-mass energy [GeV]	104.9		
Energy [GeV]	275	10	
Number of bunches	116	60	
Particles per bunch [10 <sup>10</sup> ]	6.9	17.2	
Beam current [A]	1.0	2.5	
Horizontal emittance [nm]	11.3	20.0	
Vertical emittance [nm]	1.0	1.3	
Horizontal $\beta$ -function at IP $\beta_x^*$ [cm]	80	45	
Vertical $\beta$ -function at IP $\beta_{\gamma}^{*}$ [cm]	7.2	5.6	
Horizontal/Vertical fractional betatron tunes	0.228/0.210	0.08/0.06	
Horizontal divergence at IP $\sigma_{x'}^*$ [mrad]	0.119	0.211	
Vertical divergence at IP $\sigma_{y'}^*$ [mrad]	0.119	0.152	
Horizontal beam-beam parameter $\xi_x$	0.012	0.072	
Vertical beam-beam parameter $\xi_y$	0.012	0.1	
IBS growth time longitudinal/horizontal [hr]	2.9/2.0	-	
Synchrotron radiation power [MW]	-	9.0	
Bunch length [cm]	6	0.7	
Hourglass and crab reduction factor [17]	0.94		
Luminosity $[10^{34}  \text{cm}^{-2}  \text{s}^{-1}]$	1.0		

# **Polarization Time Dependence - electrons**

- Electrons injected into the storage ring at full polarization (85%)
- Sokolov-Ternov effect (self-polarization) will re-orient spins to be anti-parallel to main dipole field → electrons will have different lifetime depending on polarization
- Bunches must be replaced relatively often to keep average polarization high
- Bunch-by-bunch polarization measurement required

### **EIC Electron Polarimetry Map**

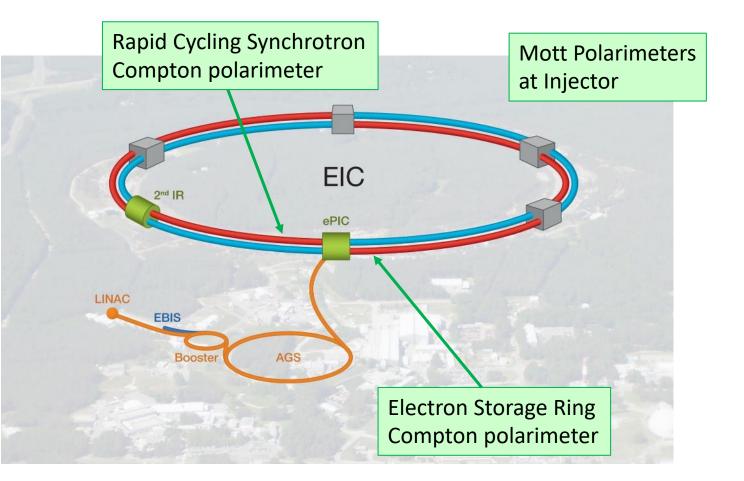

Electron Storage Ring Compton (ESR)

 $\rightarrow$  Upstream of IP6, between IP and spin rotating solenoid

- $\rightarrow$  Will measure polarization for each bunch
- → Measure both transverse and longitudinal beam polarization
- → Detect backscattered photon and scattered electron

Rapid Cycling Synchrotron Compton (RCS)

- → Primarily for machine setup less stringent precision requirements
- → Beam should be 100% transversely polarized
- → Detect backscattered photons, multiphoton mode
- $\rightarrow$  Average over several bunches

Compton polarimeter will be upstream of upstream of detector IP

At Compton interaction point, electrons have both longitudinal and transverse (horizontal) components

- → Longitudinal polarization measured via asymmetry as a function of backscattered photon/scattered electron energy
- $\rightarrow$  Transverse polarization from left-right asymmetry

Beam energy	PL	P <sub>T</sub>
5 GeV	96.5%	26.1%
10 GeV	86.4%	50.4%
18 GeV	58.1%	81.4%

### **Polarization Components at Compton**

Beam polarization will be fully longitudinal at detector IP, but accurate measurement of absolute polarization will require *simultaneous* measurement of  $P_L$  and  $P_T$  at Compton polarimeter

EIC Compton will provide first high precision measurement of  $P_{I}$  and  $P_{T}$  at the same time

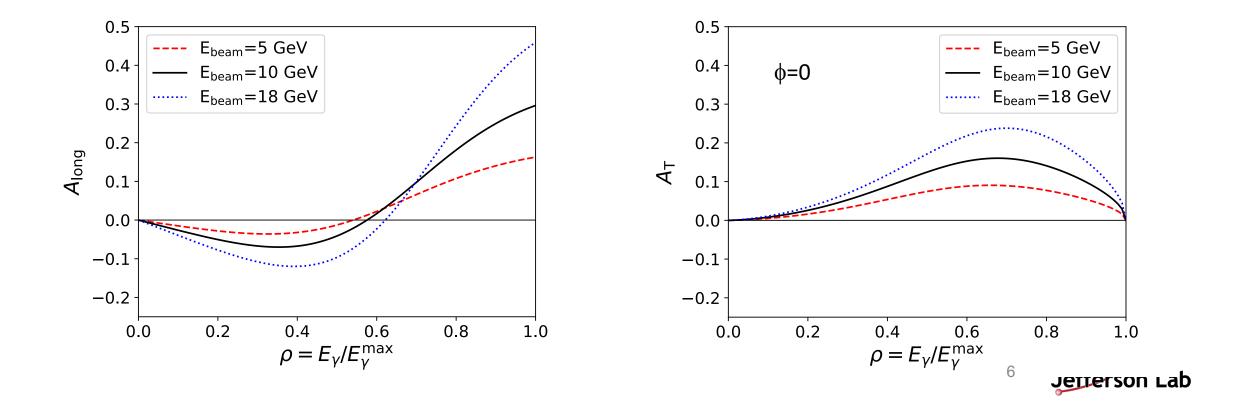

### **Polarization Measurement via Compton Polarimetry**

Compton longitudinal and transverse analyzing powers

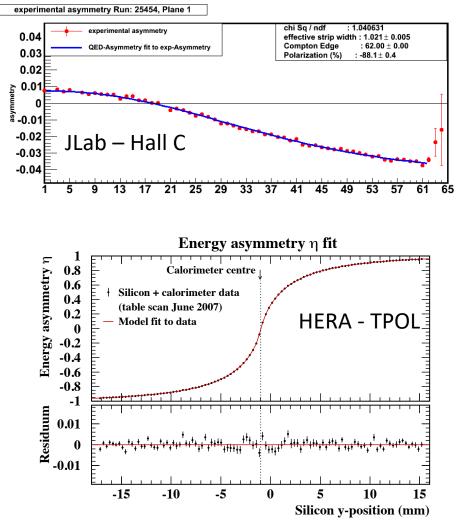

$$A_{\text{long}} = \frac{2\pi r_o^2 a}{(d\sigma/d\rho)} (1 - \rho(1+a)) \left[ 1 - \frac{1}{(1 - \rho(1-a))^2} \right]$$

$$A_{\rm T} = \frac{2\pi r_o^2 a}{(d\sigma/d\rho)} \cos\phi \left[\rho(1-a)\frac{\sqrt{4a\rho(1-\rho)}}{(1-\rho(1-a))}\right]$$

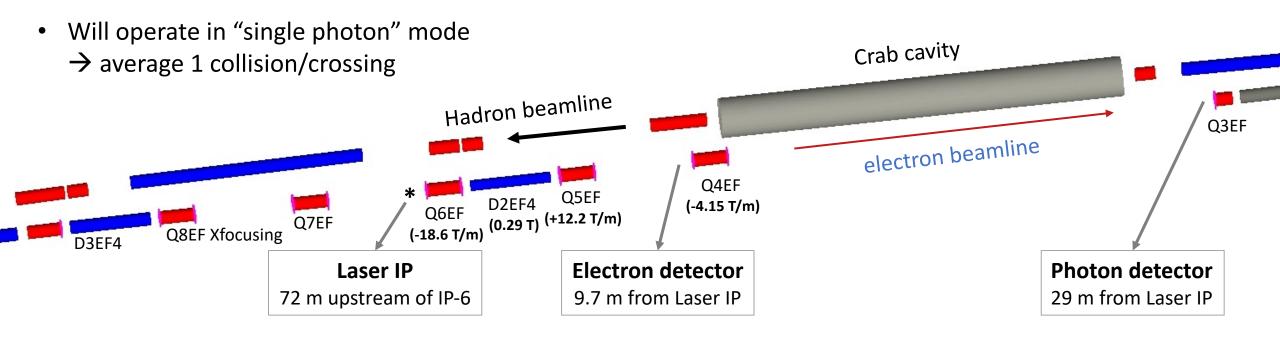

# **Compton polarimetry – lessons from previous devices**

- Longitudinal polarimetry
  - Electron detector needs sufficient segmentation to allow self-calibration
  - Photon detector integrating technique provides most robust results – perhaps not practical at EIC? → lower the threshold as much as possible
- Transverse polarimetry
  - Remove  $\eta$ -y calibration issue use highly segmented detectors at all times
  - Calorimeter resolution  $\rightarrow$  integrate over all energy?
  - Beam size/trajectory important build in sufficient beam diagnostics
- Common to both
  - Birefringence of vacuum windows can impact laser polarization → use back-reflected light (optical reversibility theorems)

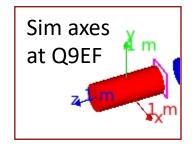

# **Electron Storage Ring Compton**

#### **Polarimeter Components:**

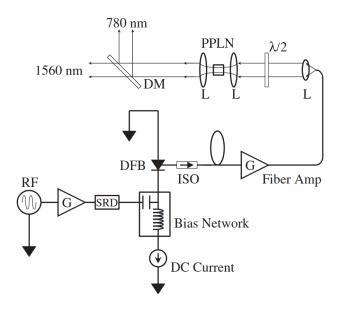

- 1. RF-pulsed laser system (under development)
- 2. Position sensitive detectors (diamond strips) for scattered electrons and backscattered photons
- 3. Calorimeter for backscattered photons

### **Compton Polarimeter Laser System**

Average of 1 backscattered photon/bunch crossing will allow Compton measurements on the ~1 minute time scale → can be achieved with pulsed laser system that provides about 5 W average power at 532 nm

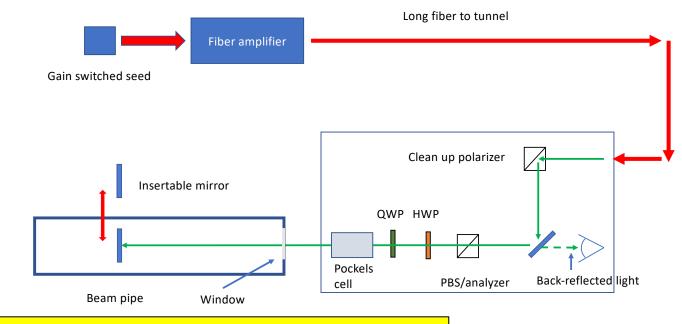

JLab injector laser system

Polarization in vacuum set using "back-reflection" technique

→ Requires remotely insertable mirror (in vacuum) Proposed laser system based on similar system used in JLab injector and LERF

- 1. Gain-switched diode seed laser variable frequency, few to 10 ps pulses @ 1064 nm
  - → Variable frequency allows optimal use at different bunch frequencies (100 MHz vs 25 MHz)
- 2. Fiber amplifier  $\rightarrow$  average power 10-20 W
- 3. Optional: Frequency doubling system (LBO or PPLN)
- 4. Insertable in-vacuum mirror for laser polarization setup

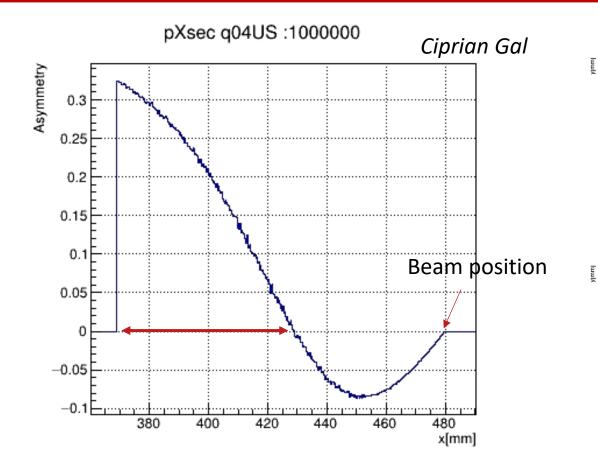

Jetterson Lab

#### Prototype system under development (C. Gal, JLab)

### **Electron Detector Size and Segmentation**

- Electron detector (horizontal) size determined by spectrum at 18 GeV (spectrum has largest horizontal spread)
  - Need to capture zero-crossing to endpoint → detector should cover at least 60 mm
- Segmentation dictated by spectrum at 5 GeV (smallest spread)
  - Scales ~ energy  $\rightarrow$  17 mm
  - Need at least 30 bins, so a strip pitch of about 550  $\mu m$  would be sufficient
- At 18 GeV, zero-crossing about 3 cm from beam
  - 5 GeV  $\rightarrow$  8-10 mm this might be challenging

Asymmetry at electron detector @18 GeV

## **Transverse Polarization Measureme**

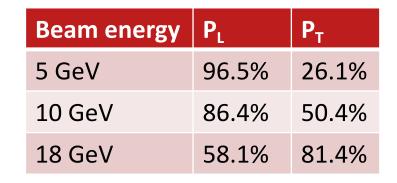

- At Compton location significant transverse beam
- → Unfortunately, this transverse polarization is in the horizontal direction
- $\rightarrow$  Same coordinate as momentum-analyzing dipole

In the absence of the dipole, the transversely polarized electrons would result in a left-right asymmetry

- → The "scattered electron cone" is much smaller than the photons
- → Left-right asymmetry is spread over much smaller distance (µm vs mm)

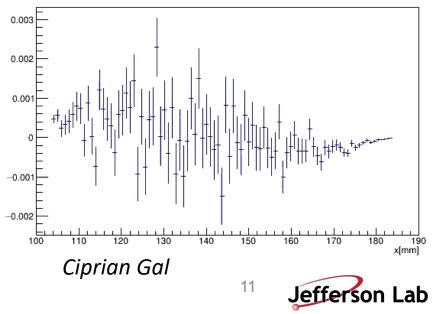

The large dispersion induced by the dipole makes measurement of the left-right asymmetry impossible

Electron detector can only be used for measurements of  $P_L$ Stony Brook University

100% transversely polarized beam

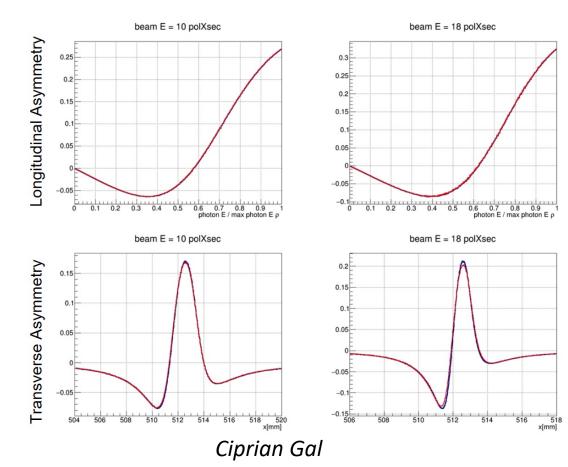

18GeV eDet(bQ9) polXsec

### **Polarization Measurement with Photon Detector**

Photon detector needs 2 components to measure both longitudinal and transverse polarization

- $\circ$  Calorimeter  $\rightarrow$  asymmetry vs. photon energy (P<sub>L</sub>)
- $\circ$  Position sensitive detector  $\rightarrow$  left-right asymmetry (P<sub>T</sub>)

Beam energy	PL	P <sub>T</sub>
5 GeV	96.5%	26.1%
10 GeV	86.4%	50.4%
18 GeV	58.1%	81.4%

Transverse size of detectors determined by backscattered photon cone at low energy

- $\rightarrow$  +/- 2 cm adequate at 5 GeV
- → Longitudinal measurement requires good energy resolution from ~0 (as low as possible) to 3 GeV
- $\rightarrow$  Fast time response also needed (10 ns bunch spacing)
- → PbWO4 a possible candidate (slow component may be an issue)

Position sensitive detector segmentation determined by highest energy  $\rightarrow$  18 GeV

→ More investigation needed, but segmentation on the order of 100-400  $\mu$ m should work

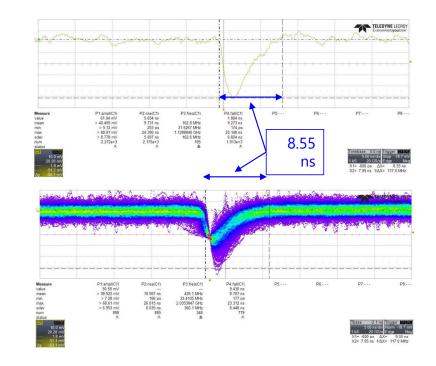

## **Position Sensitive Detectors**

- Requirements for position sensitive detectors
  - Radiation hard
  - Fast response (needed for bunch-by-bunch measurements)
  - High granularity (down to 25 μm pitch)

Size determined by 5 GeV hit distributions, segmentation by 18 GeV distributions

Diamond strip detectors have been used successfully at JLab in Compton polarimeters

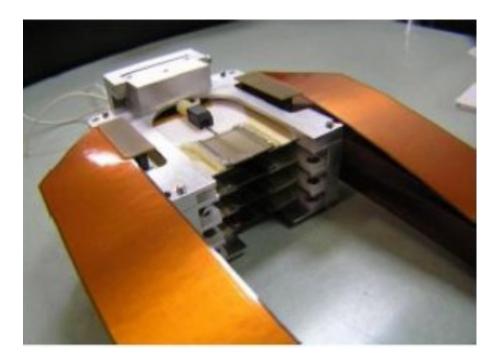

- → No performance degradation after 10 Mrad dose during Q-Weak experiment @ JLab
- → Intrinsic time response is fast, but small signals require significant amplification custom electronics/ASIC will be required

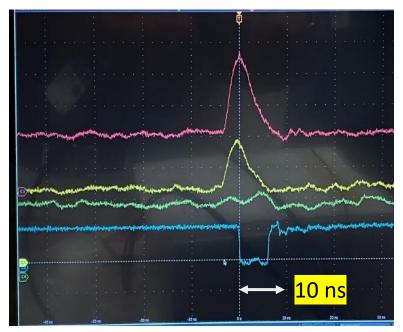

### 500 $\mu$ m pCVD diamond w/TOTEM electronics

### **Diamond strip detectors @ JLab**

#### Signals from CALYPSO/FLAT32 prototype

Hall C diamond strip detector

New diamond strip detectors under development for JLab/Hall A MOLLER experiments

- $\rightarrow$  Size optimized for 11 GeV operation
- → Q-Weak detector had amplifier discriminator outside vacuum will use ASIC chip mounted on detector board

New "FLAT32" chip based on "CALYPSO" (used at LHC) under development – already meets EIC requirements

### **Photon Calorimeter**

- Good energy resolution required for longitudinal polarization measurements, but fast time response required for bunch-by-bunch measurements
- Tungsten-powder calorimeter (similar to STAR Forward Upgrade) satisfies timing requirements for Compton polarimeters
  - Scintillating fiber embedded in tungsten powder
  - Ample experience with such detectors at BNL
- Detector size 16 x 16 mm<sup>2</sup>
- Initially, thought long time component ruled out leadtungstate
  - Recent publication suggests time response at room temperature may be acceptable

**Table 2**. Measured luminescence properties of doped PbWO<sub>4</sub> scintillator crystals on our apparatus for a mean energy deposited of 432 keV.  $Y_{xx}$  stands for photo-electron yields,  $\tau_{XX}$ , for scintillation time constants. The Cherenkov contribution to yield, 0.80 photo-electron, is included in the total luminescence Yield. Second part: computed values of systematic errors on measurements (see paragraph 6)

15

### **Detector Simulations**

- → Need high position resolution for backscattered photons for transverse polarization measurement
- → Best results from longitudinally segmented calorimeter with (x-y) diamond strips

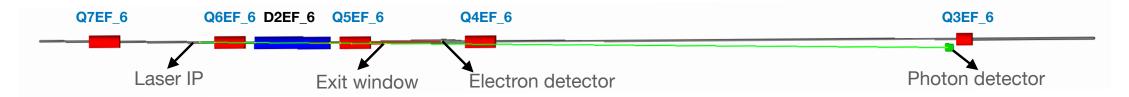

Overall efficiency 60% w/adequate resolution

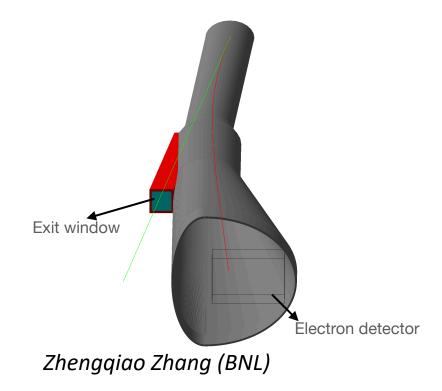

### **Beamline Design and Synchrotron Backgrounds**

- Beampipe design for region downstream of laser-electron beam collisions underway
- Need photon exit window and room to accommodate scattered electrons and electron detector
- Impedance likely an issue electron detector may need to be outside beam pipe, but this could limit how much of the spectrum we can detect
- Synchrotron backgrounds at 18 GeV require 2 cm tungsten shield!

   → Although polarimeter location has been chosen, need to iterate with machine group to minimize synchrotron backgrounds (dipole bend too large)

# **Rapid Cycling Synchrotron (RCS) Compton Polarimeter**

### **RCS properties**

- RCS accelerates electron bunches from 0.4 GeV to full beam energy (5-18 GeV)
- Bunch frequency  $\rightarrow$  2 Hz
- Bunch charge → up to 28 nA
- Ramping time = 100 ms

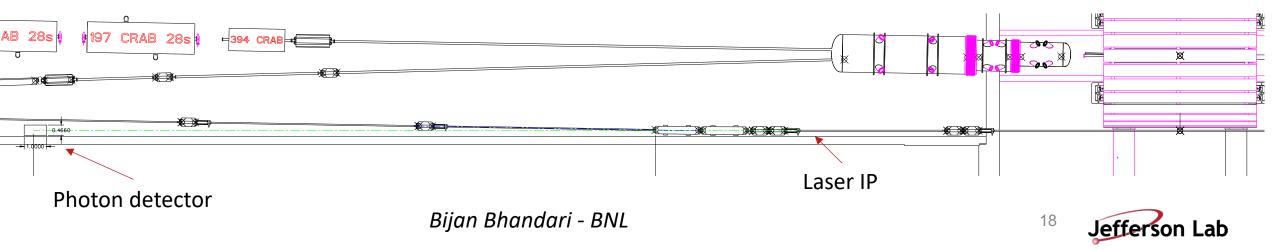

### Polarimetry challenges

- Analyzing power often depends on beam energy
- Low average current
- Bunch lifetime is short

Compton polarimeter can also be used for measurement of polarization in RCS

- → Measurements will be averaged over several bunches can tag accelerating bunches to get information on bunches at fixed energy
- → Requires measurement in multiphoton mode (many backscattered photons/electron bunch)

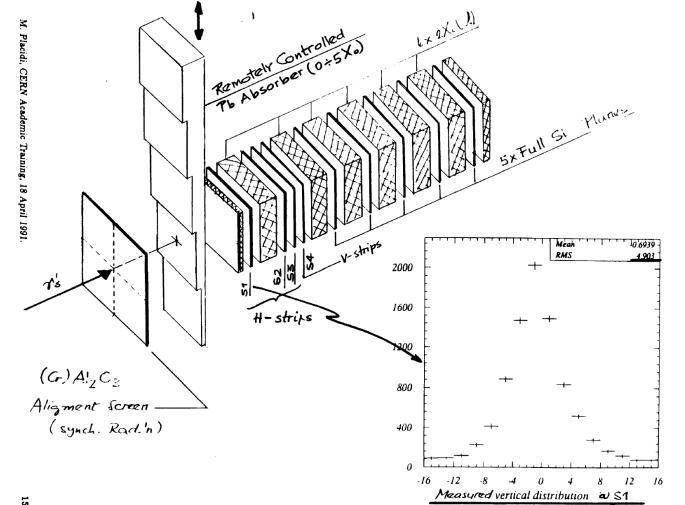

Highest precision transverse Compton polarimeter operated in single photon mode (HERA)

 $\rightarrow$  RCS requires position sensitive measurement in **multi-photon** mode

Need highly segmented detector sensitive to signal size (not just counts above threshold)

 $\rightarrow$  LEP polarimeter operated in this fashion, although with relatively low precision

# Summary

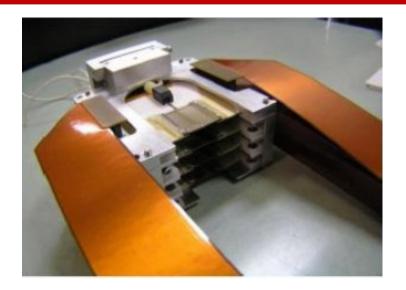

- Electron polarimetry at EIC has challenging requirements
  - Bunch-by-bunch polarization measurement with short times between bunches (as low as 10 ns)
  - -High precision: dP/P=1% (or better)
  - Simultaneous measurement of longitudinal and transverse components
- EIC Compton polarimeter in storage ring must meet all these requirements
  - Simultaneous detection of the backscattered photons and scattered electrons will allow high precision for both longitudinal and transverse polarization
  - Fast detectors required due to bunch structure
- RCS Compton polarimeter needed to provide information on electron polarization during acceleration
  - -Will operate in multi-photon mode (several thousand photons/bunch crossing)
  - -Less stringent requirements for absolute precision

### **EXTRA**

### **ESR Compton Detector Technology**

JLab Hall C diamond detector

Several choices feasible for position sensitive detectors

- $\rightarrow$  Diamond strip detectors are baseline choice
  - Radiation hard
  - Fast time response
  - Compatible with segmentation requirements
  - ASIC under development for LHC diamond detectors compatible with EIC timing requirements

Tungsten-powder calorimeter

Photon calorimeter more challenging

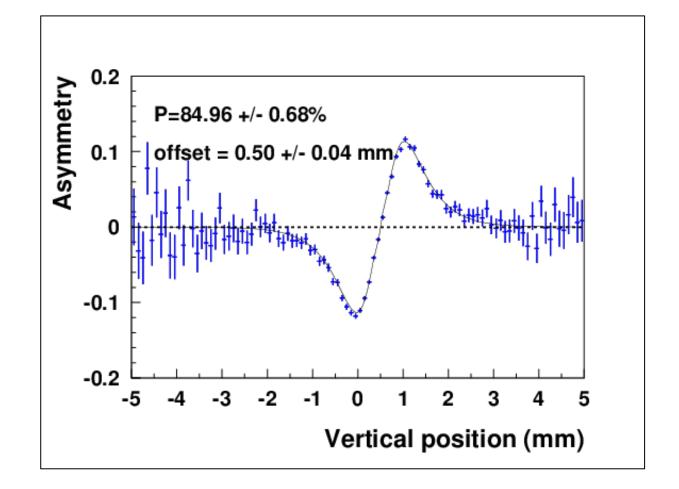

- → Timing requirements suggest lower resolution calorimeter must be used
- → OK for transverse measurement, but reduces precision on longitudinal

Differential measurement of asymmetry vs. position at detector allows us to incorporate offsets in the fit

Example using Toy MC for integrating mode asymmetry vs. y assuming 0.1 mm segmentation (240 bunches)
→ Sufficient position resolution would allow determination of arbitrary offset in spectrum

→ Requires detector operating in integrating mode (~10,000 photons/bunch) with signal proportional to number of photons in each channel

23

#### The needed time $t_D$ to achieve an accuracy $\Delta P_e/P_e$ is then

### **Compton Laser System Requirem**

$$t_D^{-1} = \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < \frac{A_l^2}{1 - P_e^2 P_{\gamma}^2 A_l^2} > \simeq \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 P_{\gamma}^2 P_{\gamma}^2 \sigma_t < A_l^2 > 2 \mathcal{L} \left(\frac{\Delta P_e}{P_e}\right)^2 P_e^2 P_{\gamma}^2 P_$$

#### Ciprian Gal

Laser power constraint: sufficient power to provide ~ 1 backscattered photon/bunch-laser crossing → Want to make "single photon" measurements – not integrating

532 nm laser with ~5 W average power at same frequency as EIC electron bunches sufficient

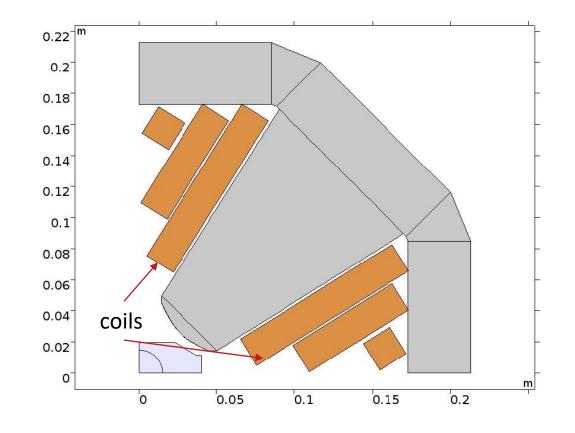

StReBulting measurement times (for differential measurement, dP/P=1%) as noted above – easily meets beam lifetime constraints

Photons will not clear beamline magnet apertures in some cases
→ Quad inner aperture: R= 6 cm
→ Quad outer radius = 25 cm

Depending on final layout, will need to modify one or more quads to allow clear aperture for backscattered photons

If backscattered photons traverse ironfree region – coils can likely/hopefully be modified to accommodate → For 1<sup>st</sup> option, one quad may require a hole in the iron – but this should not have large impact on quad performance

Quad cross-section

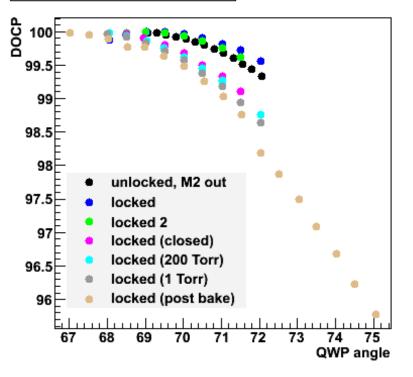

Relatively straightforward to prepare/determine laser polarization before entering beamline

- → Stress on entrance window can introduce significant birefringence
- →Nearly impossible to measure directly without significant instrumentation in vacuum

Measurements at JLab suggest these effects can't be ignored

State 1: DOCP in exit line

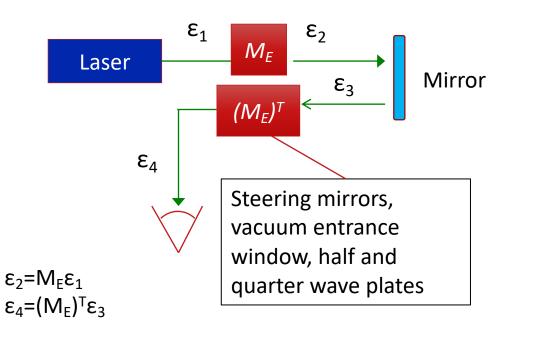

JLab laser polarization measurements through 2 vacuum windows → Tightening bolts on flanges, vacuum stress has significant impact

### Laser Polarization – Optical reversibility theorems

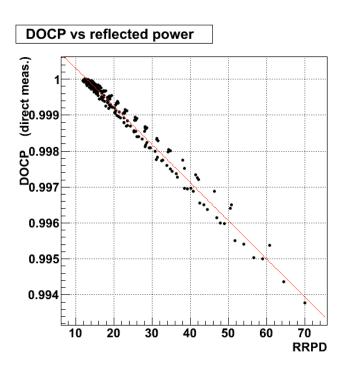

Propagation of light through the vacuum window to the IP can be described by matrix,  $M_E \rightarrow Light$  propagating in opposite direction described by transpose matrix,  $(M_E)^T \rightarrow If$  input polarization ( $\epsilon_1$ ) linear, polarization at cavity ( $\epsilon_2$ ) circular only if polarization of reflected light ( $\epsilon_4$ ) linear and orthogonal to input\*

 $\varepsilon_4 = (M_F)^T M_F \varepsilon_1$ 

Laser polarization at a mirror (inside vacuum) can be set/determined by monitoring the back-reflected light in a single photodiode

→ Used this technique
 at JLab to constrain
 laser polarization to
 ~0.1%

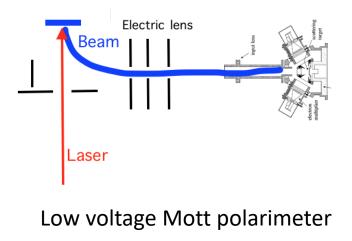

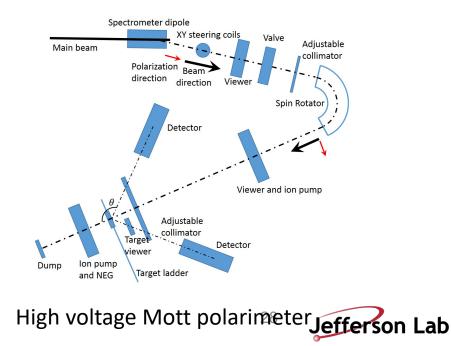

\*J. Opt. Soc. Am. A/Vol. 10, No. 10/October 1993

EIC will make use of two Mott polarimeters to measure the electron polarization from the source

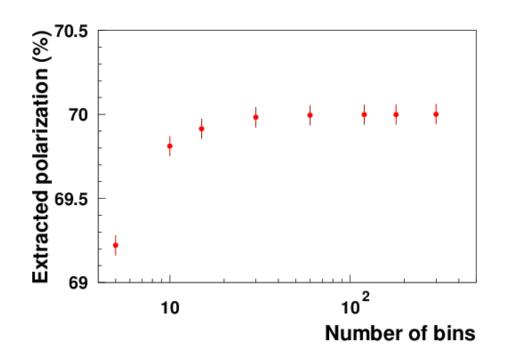

- 1. Low voltage Mott polarimeter
- → Measure polarization at 20 keV immediately after photocathode
- 2. High voltage Mott polarimeter
- → Measure at 300 keV, in the beamline, before electron bunching
- → Requires spin rotator to change electron from longitudinal to transverse spin

Detector segmentation driven by requirement to be able to extract polarization (fit asymmetry) without any corrections due to detector resolution (see SLD Compton)

→ Studies with toy Monte Carlo suggest that about 30 bins (strips) between asymmetry zero crossing and endpoint results in corrections <0.1%

### Luminosity

Luminosity for CW laser colliding with electron beam at non-zero crossing angle:

$$\mathcal{L} = \frac{(1 + \cos \alpha_c)}{\sqrt{2\pi}} \frac{I_e}{e} \frac{P_L \lambda}{hc^2} \frac{1}{\sqrt{\sigma_e^2 + \sigma_\gamma^2}} \frac{1}{\sin \alpha_c}$$

Pulsed laser:

$$\mathcal{L} = f_{coll} N_{\gamma} N_e \frac{\cos\left(\alpha_c/2\right)}{2\pi} \frac{1}{\sqrt{\sigma_{x,\gamma}^2 + \sigma_{x,e}^2}} \frac{1}{\sqrt{(\sigma_{y,\gamma}^2 + \sigma_{y,e}^2)\cos^2\left(\alpha_c/2\right) + (\sigma_{z,\gamma}^2 + \sigma_{z,e}^2)\sin^2\left(\alpha_c/2\right)}}$$

 $N_{\gamma(e)}$  = number of photons (electrons) per bunch

Assumes beam sizes constant over region of overlap (ignores "hourglass effect")

Beam size at interaction point with laser dictates luminosity (for given beam current and laser/electron beam crossing angle)

Electron Polarimetry Systematics	Beam energy	PL	P <sub>T</sub>
	5 GeV	96.5%	26.1%
State of the art for Compton polarimetry:	10 GeV	86.4%	50.4%
Longitudinal:	18 GeV	58.1%	81.4%

Longitudinal:

SLD @ SLAC: dP/P=0.5%  $\rightarrow$  Electron detector in multi-photon mode Q-Weak in Hall C @ JLab: dP/P=0.59%  $\rightarrow$  Electron detector, counting mode CREX in Hall A @ JLab: dP/P=0.44%  $\rightarrow$  Photon detector, integrating mode

### Transverse:

TPOL @ HERA: dP/P=1.87% → Photon detector in counting mode

Total polarization extraction will rely on two quasi-independent measurements While 0.5% for P<sub>L</sub> is plausible, P<sub>T</sub> is less certain  $\rightarrow$  1%?

At 18 GeV this results in dP/P=0.86% at 18 GeV
