Science

# Why large phase space beams?

- Positron beams will be much larger in phase space than nominal electron beams at CEBAF
- We want to understand the transport of larger phase space beams in 12 GeV CEBAF
  - Do these larger beams fit in the machine?
  - How does the emittance evolve for higher number of passes?
  - Limits on positron phase space?

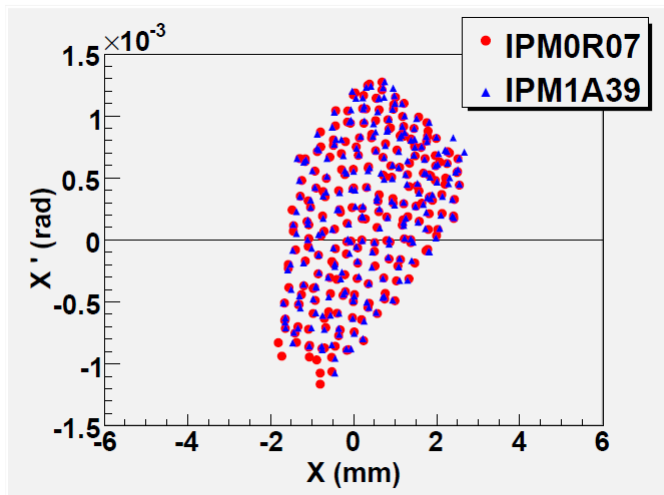

Table 1: Simulated Emittances in CEBAF [4], [5]

Area	Electrons			Positrons		
	$\delta p/p[\times 10^{-3}]$	$\epsilon_x[nm]$	$\epsilon_y[nm]$	$\delta p/p[\times 10^{-3}]$	$\epsilon_x[nm]$	$\epsilon_y[nm]$

S. Golge Ph.D. thesis

Simulated emittance evolution in CEBAF for electron and positron beams  
Y. Roblin JLAB-TN-21-043

# Approach: design, build, install a device to degrade beams

- Funded 2 year JLab LDRD project proposed 3 objectives:
  - Design and build a beamline to make electron beams “look like” positron beams
  - Measure machine acceptance and emittance evolution in CEBAF
  - Transport positrons through parts of the CEBAF injector

*FY 2023 LDRD Proposal*

## **FY 2023 LDRD Proposal**

**Program: DRD**

**Proposal Title:** Assessing CEBAF using degraded beams for the Ce+BAF positron upgrade

**Principal Investigator, Division:** Amy Sy, Accelerator Division

**Co-Investigator, Division:**

**Contributors, Division:** Dennis Turner, Accelerator Division; Yves Roblin, Accelerator Division

<b>Budget</b>	<b>Total</b>	<b>FY23</b>	<b>FY24</b>	<b>FY25</b>
<b>(\$K)</b>	376.4	237.7	138.7	--

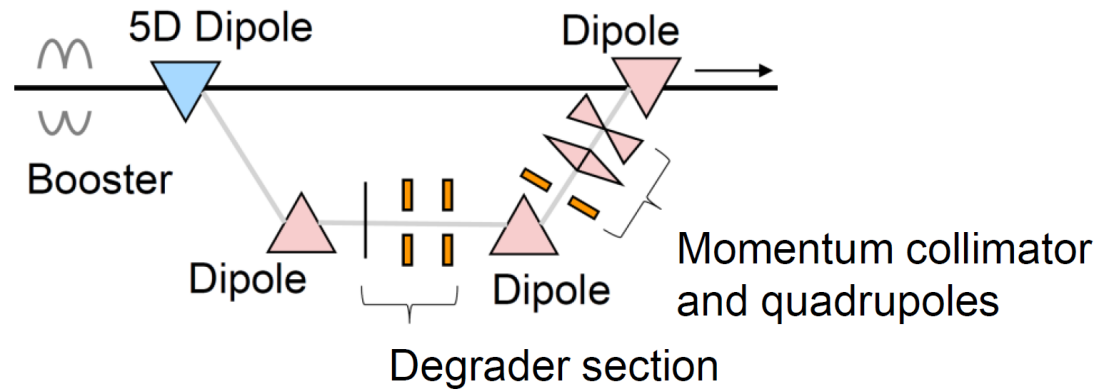

# Year 1 focused on design

- Major components include the degrader target and apertures to collimate very large angle particles
- Many ways to implement

Original Design

More flexible

More complicated  
and expensive

Final Design

Compact

Easier to implement

Less flexible

# Target materials and thicknesses simulated

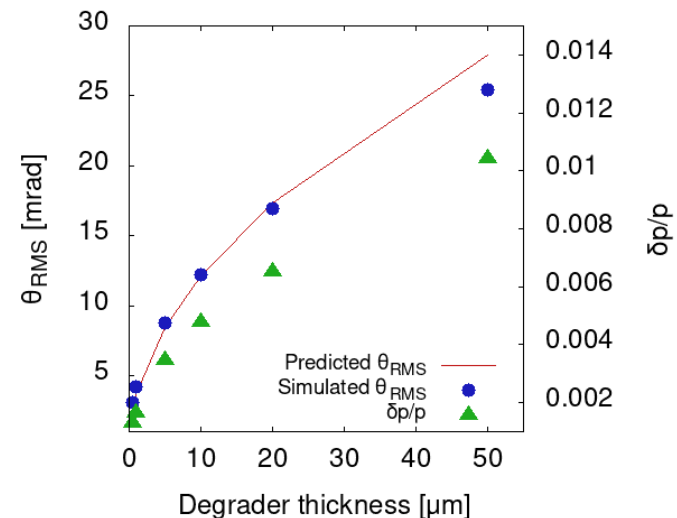

- Started with high-Z materials, like W for PEPPo
- Higher fraction of radiation length increases induced angular and energy spread
- Balance with losses due to collimation
- Choice of straight-ahead degrader implementation motivated shift to low-Z target material: Carbon, 1-10  $\mu\text{m}$  thick

$$\theta_{rms} = \frac{13.6}{E[\text{MeV}]} \sqrt{\frac{w}{X_0}} \left(1 + 0.038 \ln \frac{w}{X_0}\right)$$

w: target thickness

$X_0$ : material radiation length

RMS polar angle due to multiple scattering

RMS polar angle and energy spread in Carbon targets

# Two apertures to act as an emittance filter

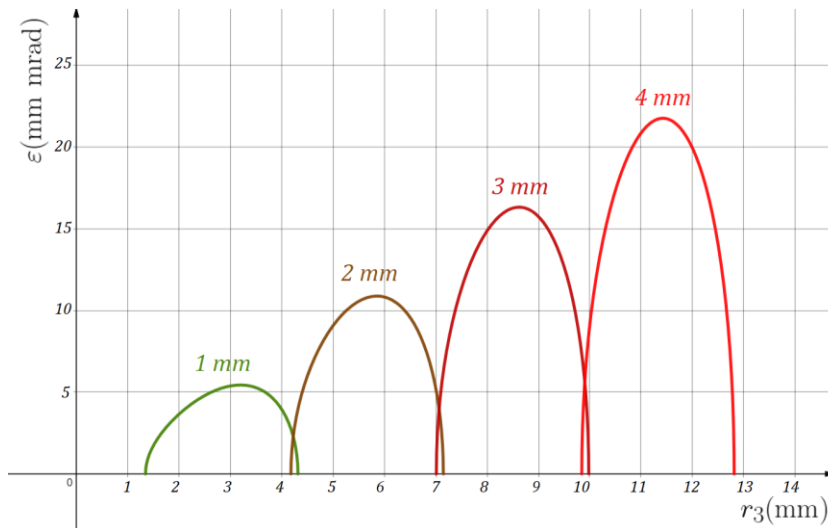

- Maximum transmitted emittance determined by aperture size and spacing to target location

$$\varepsilon^2 = \frac{\left[ \frac{r_2^2(r_1^2 + r_3^2 - 2r_2^2)}{2} - \frac{(r_1^2 - r_3^2)^2}{16} \right]}{L^2}$$

$r_1, r_2, r_3$  are aperture radii,  $L$  is distance between apertures  
[JLAB-TN-89-191, JLAB-TN-90-261]

Generalized for  
arbitrary spacing  
[V. Lizarraga]

$$\varepsilon^2 = r_2^2 \frac{L_1(r_3^2 - r_2^2) + L_2(r_1^2 - r_2^2)}{L_1 L_2 (L_1 + L_2)} - \left( \frac{L_2^2(r_1^2 - r_2^2) - L_1^2(r_3^2 - r_2^2)}{2L_1 L_2 (L_1 + L_2)} \right)^2$$

We will have two hole sizes per  
aperture assembly

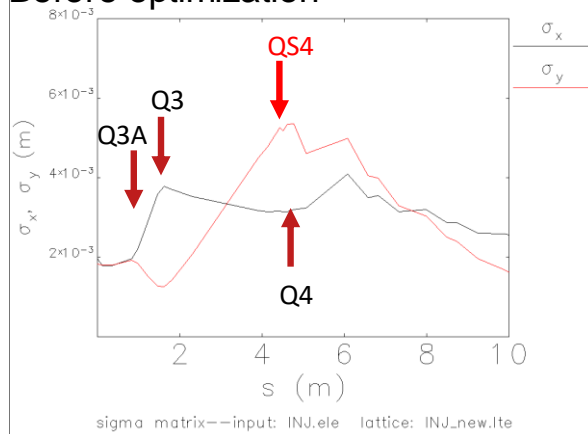

Maximum transmitted emittance  
values are a few orders of  
magnitude larger than emittance  
near this location now

# Optics optimization for maximizing transmission

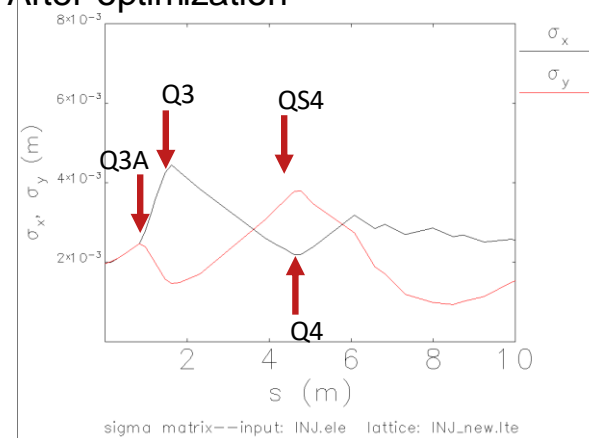

- From Elegant:  $p=6.74$  MeV/c;  $\sigma_x=0.85$  mm;  $dpp=1e-3$
- Degraded beam distribution from GEANT4
- Back to Elegant for further beam transport

Before optimization

After optimization

Estimated transmission for thinnest target > 95%

Estimated transmission for thickest target > 65%

# Moving towards reality: engineering design

[G. Hays, S. Gregory]

# Degrader girder location in CEBAF

# Summary

---

- Because positron beams will be much larger in phase space than nominal electron beams, we want to understand the transport of large phase space beams in CEBAF
- We are building a device to generate large phase space beams through multiple scattering in thin carbon targets
- The degraded beam parameter space available from this device has substantial overlap with the parameter range of interest
- We are working towards being ready to install during the summer 2024 SAD
